# MEASURING THE IMPACTS OF BUSHFIRE ON HUMAN FATALITIES AND BUILDING LOSSES

**Rob van den Honert, Katharine Haynes, Lucinda Coates**  
Risk Frontiers, Macquarie University, NSW

An Australian Government Initiative

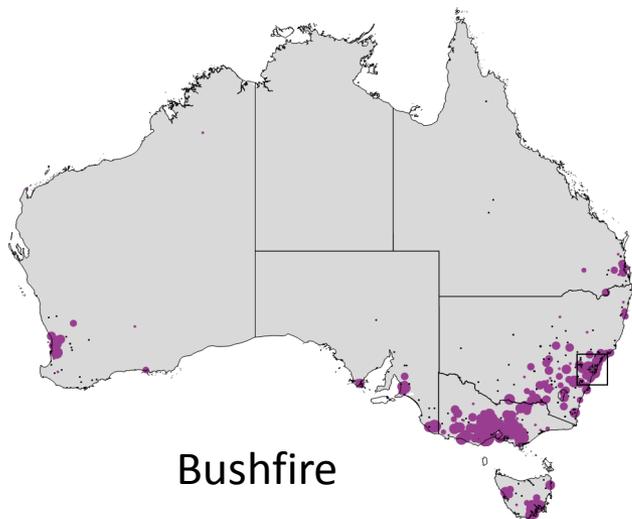

# Objectives of the CRC project

To measure and understand the impacts of natural hazards in terms of

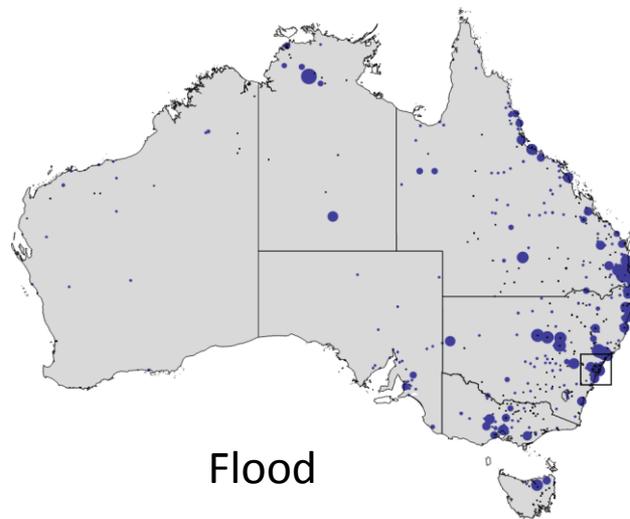

- the toll on human life and injuries, and
- building losses and damage

in order to provide an evidence base for emergency management policy and practise.

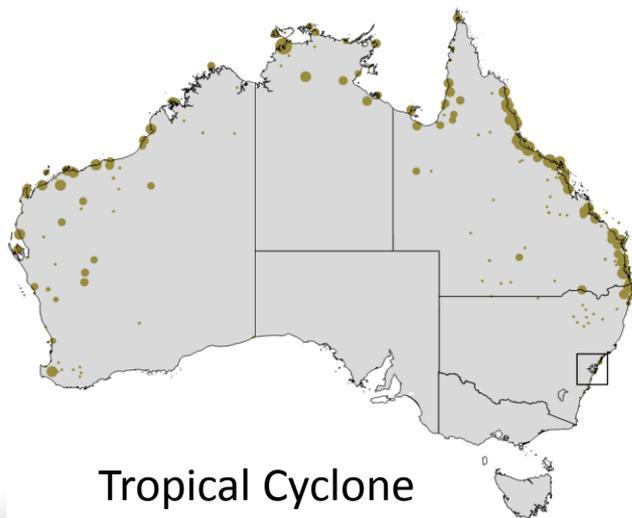

# PerilAUS: A History of Natural Disasters

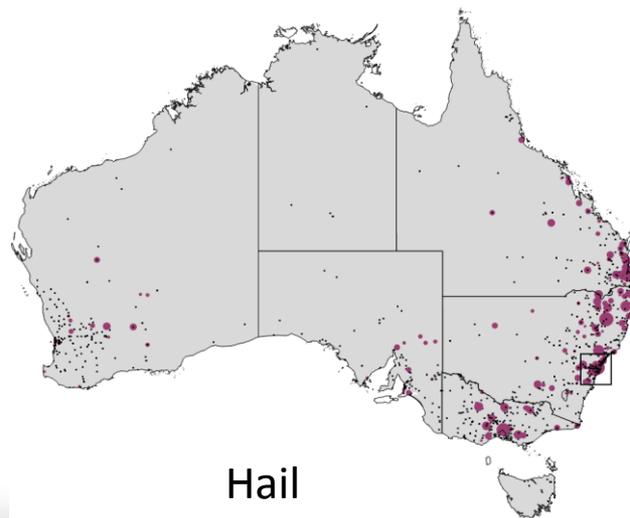

Bushfire

Flood

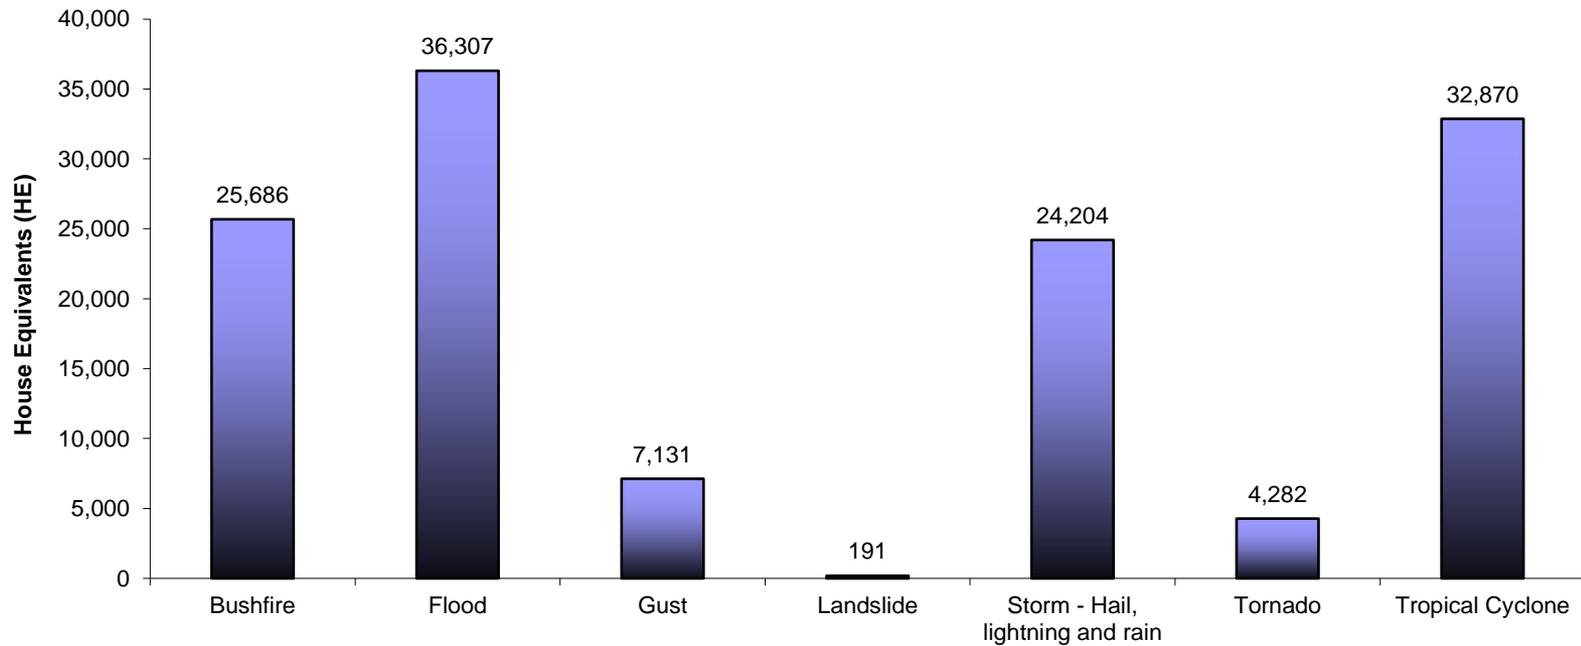

Tropical Cyclone

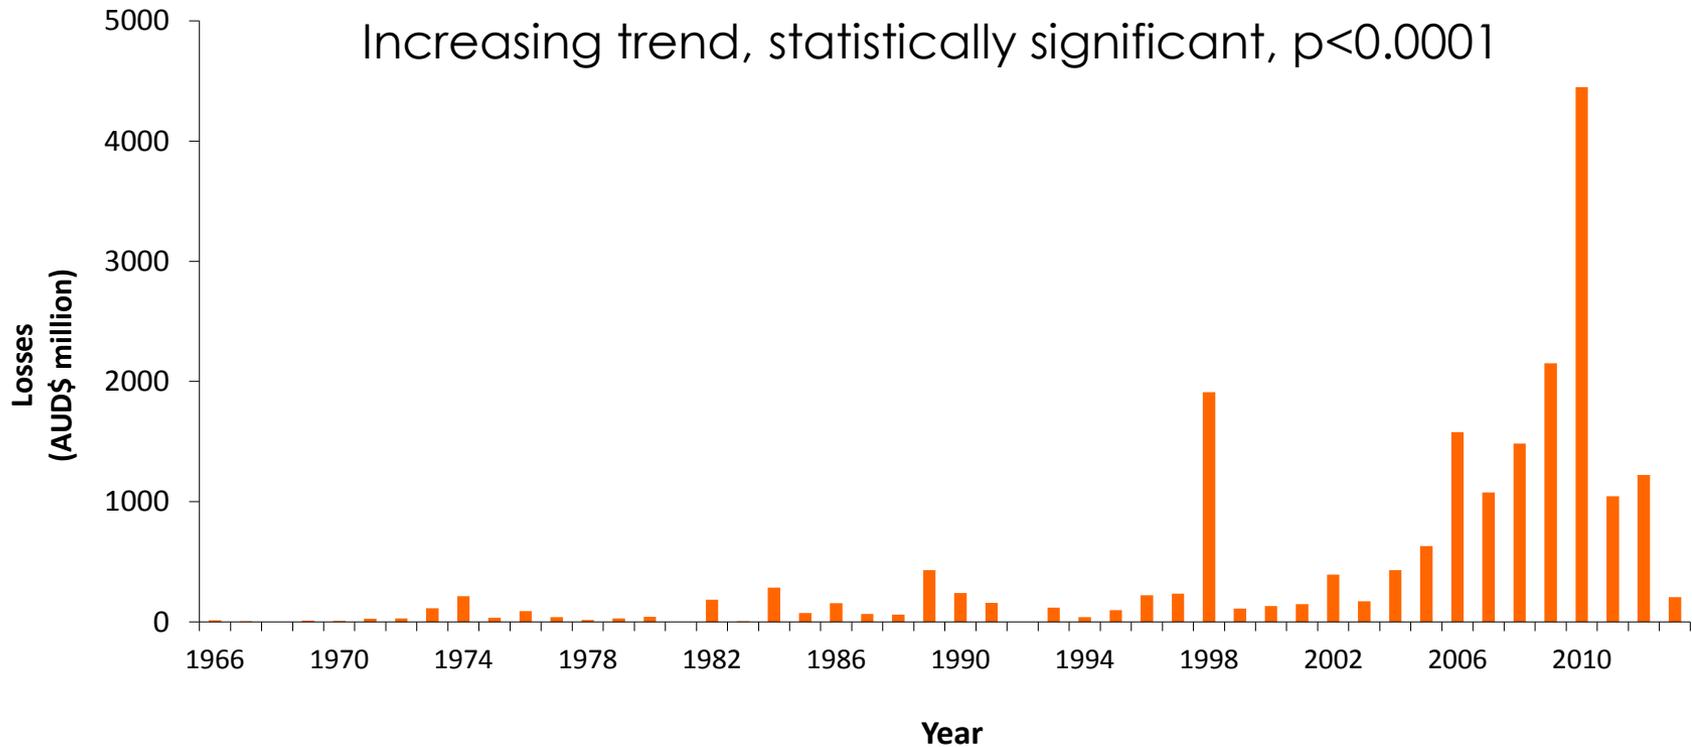

Hail

# PerilAUS: A History of Natural Disasters

**Natural hazard losses in Australia**  
Total HE losses by hazard type, 1925/6 to 2010/11

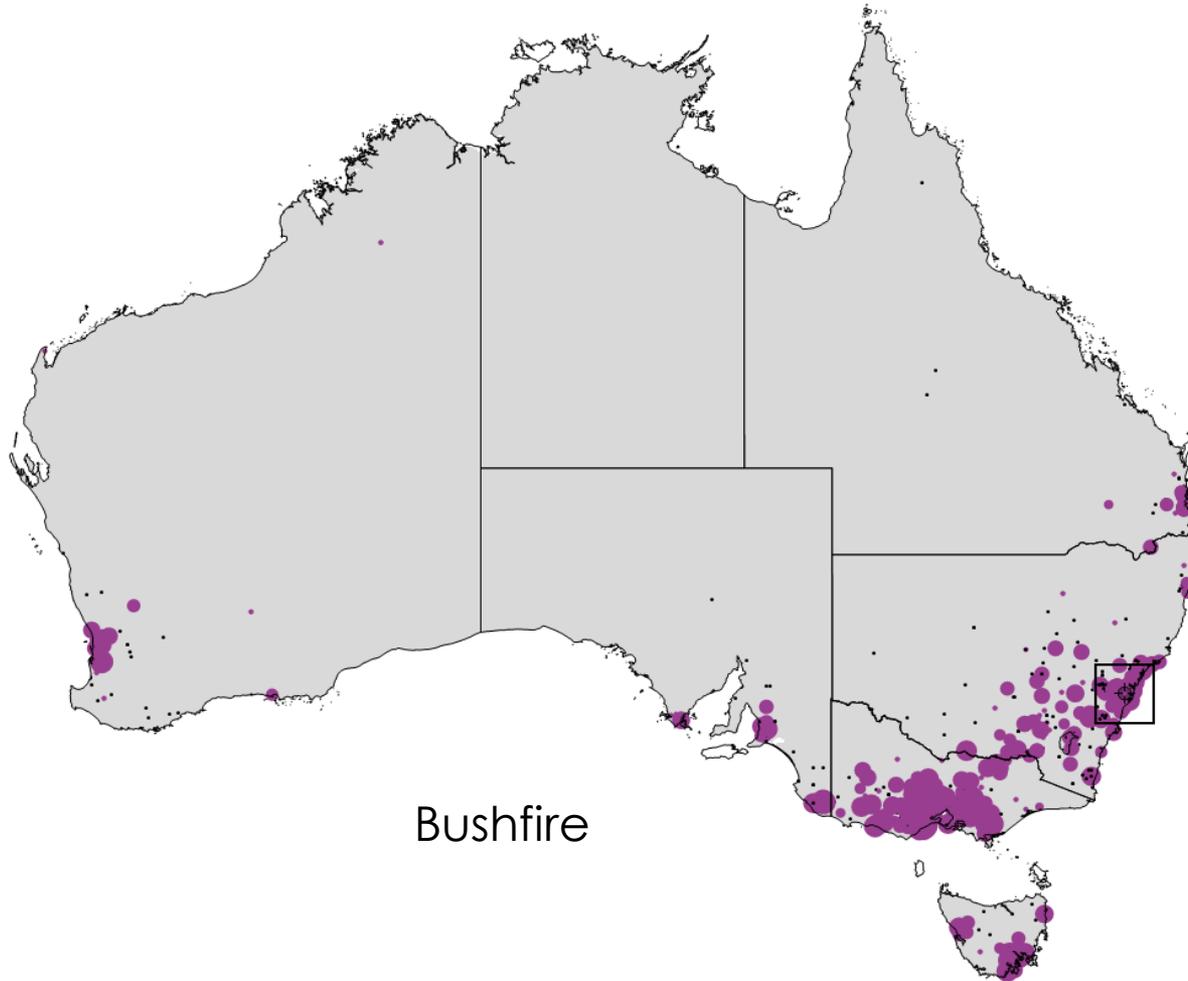

# Australian weather-related natural disaster losses

(Crompton et al. 2010)

# PerilAUS: A history of bushfires

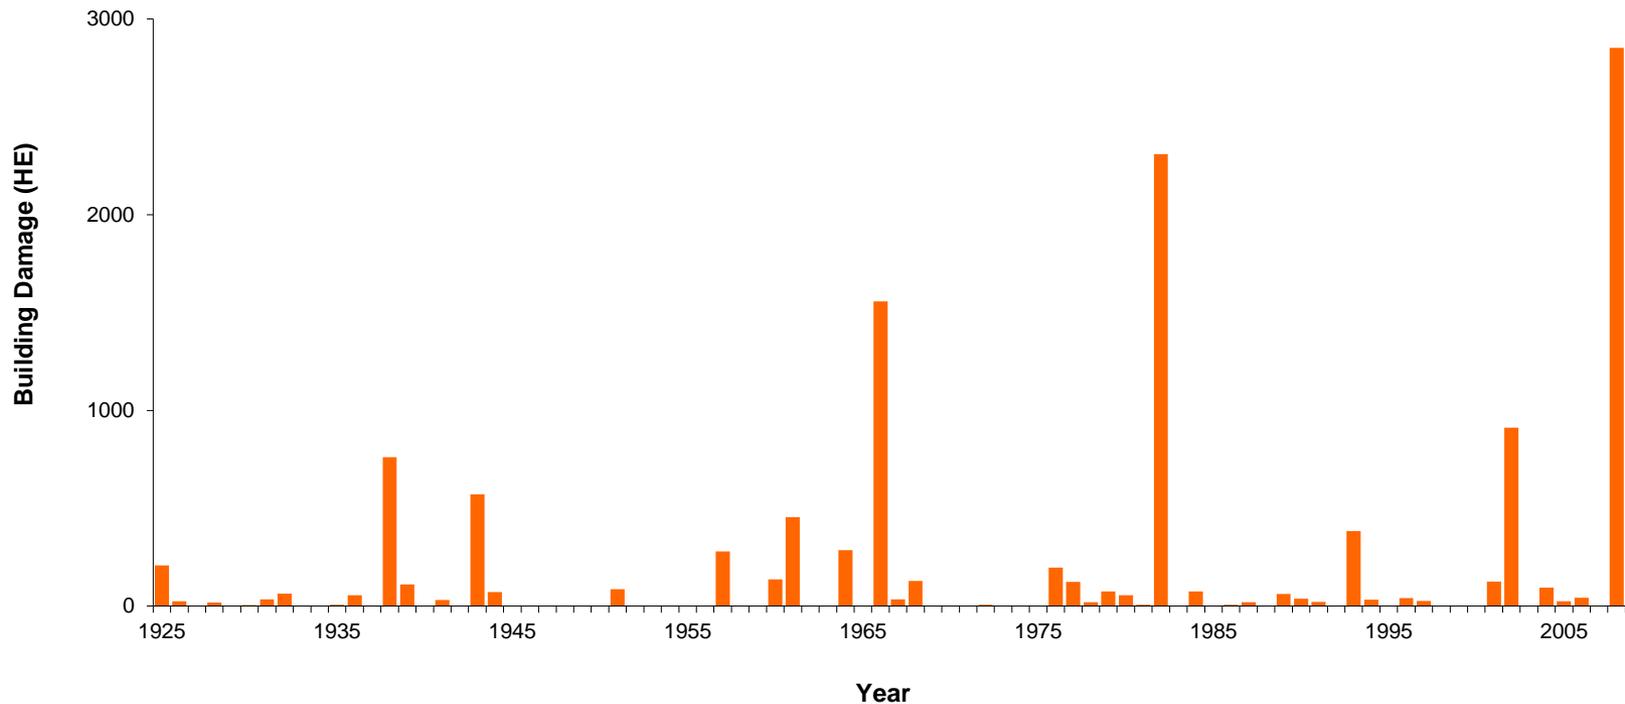

Historical event losses since 1926. Source: Risk Frontiers' *PerilAUS* database

[bnhcrc.com.au](http://bnhcrc.com.au)

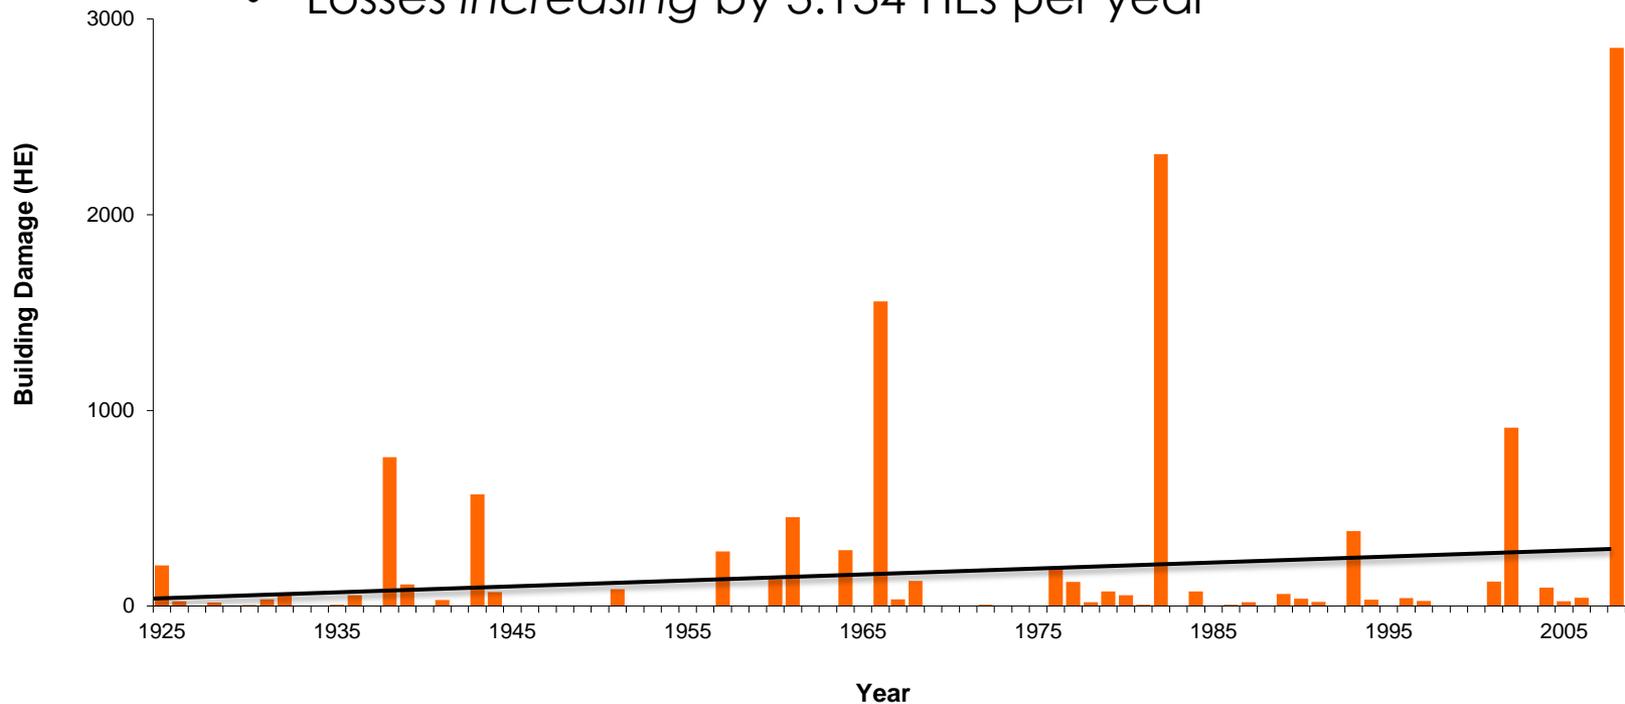

# Building damage due to bushfire, 1925-2009

- Bushfire losses occur consistently across time
- HE – “house equivalent”

# Building damage due to bushfire, 1925-2009

- Bushfire losses occur consistently across time
- HE – “house equivalent”
- A nearly statistically significant increasing trend ( $p=0.12$ )
- Losses *increasing* by 3.134 HEs per year

# Australia – coastal developments

Gold Coast Main Beach  
circa 1970

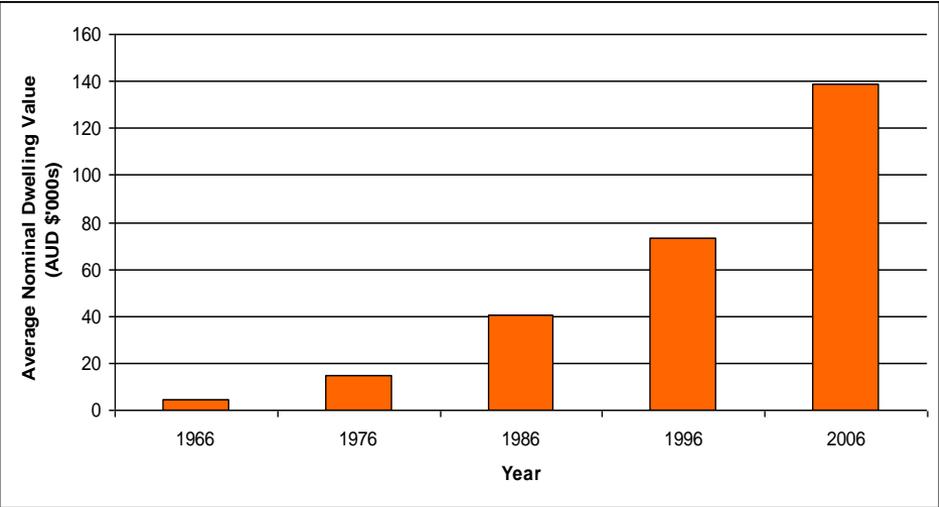

Gold Coast Main Beach  
2003

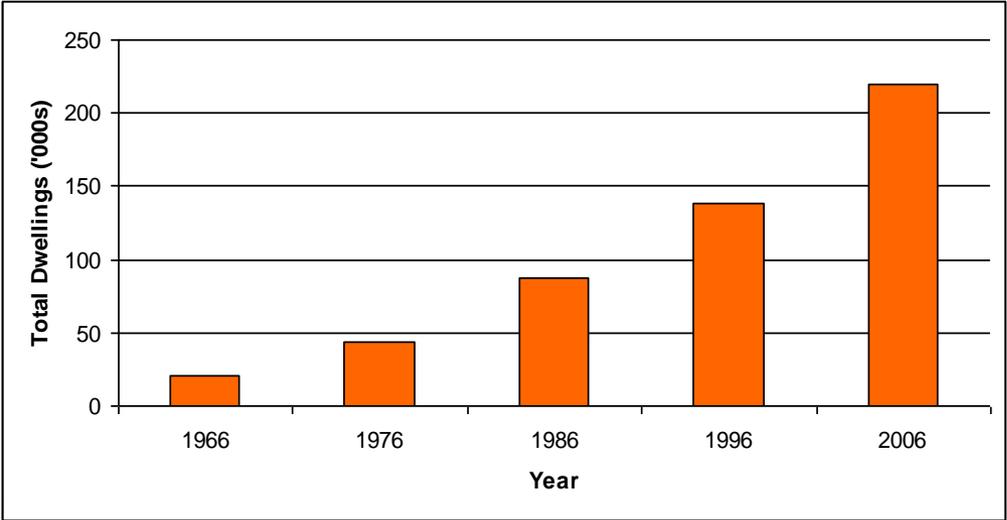

Source: Local Studies Library, Gold Coast City Council

# Gold Coast - Tweed Heads

Cost per dwelling

Number of dwellings

# Normalisation of natural disaster loss data

- *Normalisation* refers to the process of adjusting historical losses for known societal changes (e.g. numbers of homes, the value of these homes, and improvements in building codes and construction).
- Normalised losses effectively estimate the losses as if *past events* were to impact *present-day society* (i.e. an ‘apples-versus-apples’ comparison of event losses over time).

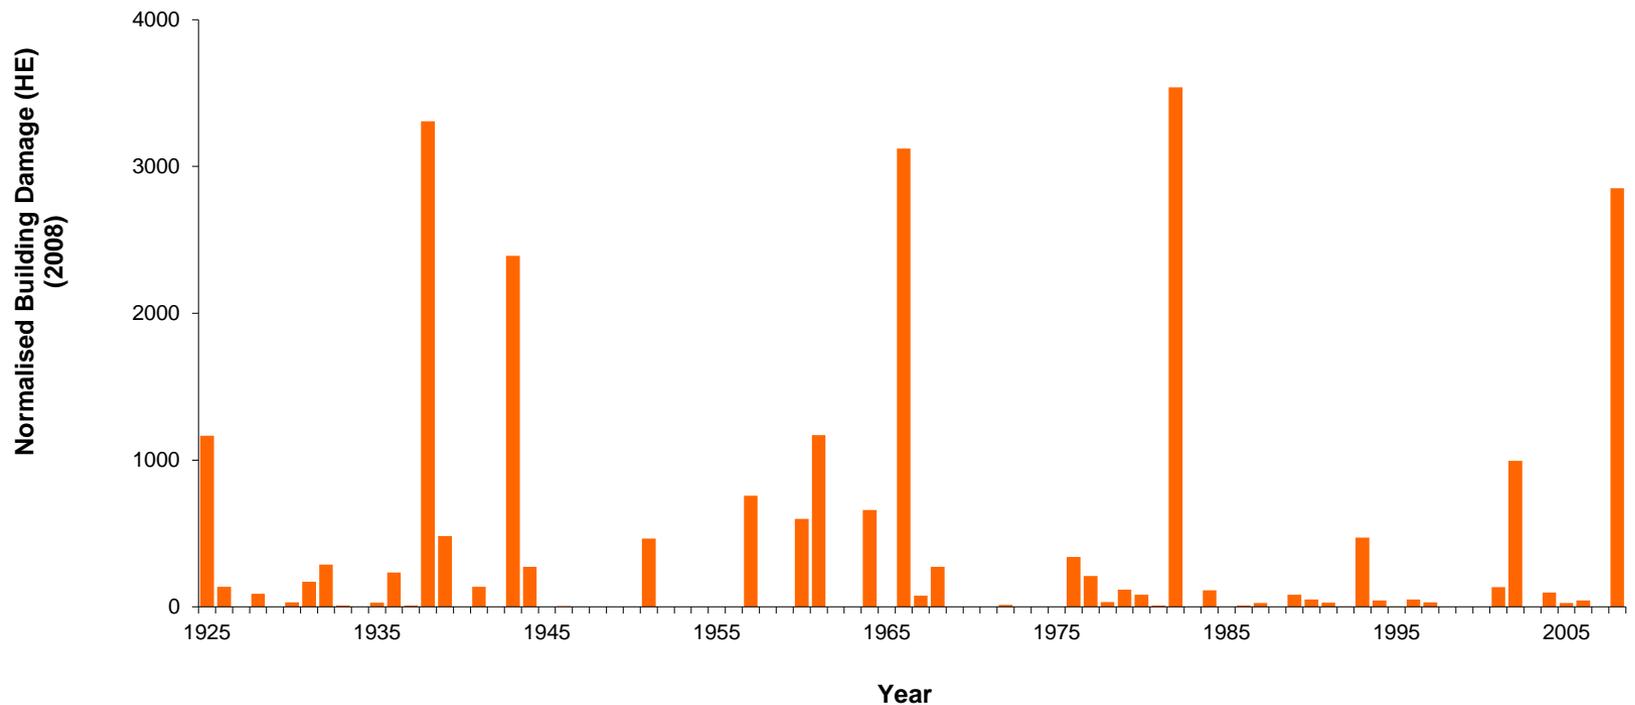

# Major Australian Disaster Losses (normalised)

What perils have caused the greatest losses (in \$ terms)?

Event	Ranking	Year	Normalised cost
Sydney hailstorm	1	1999	AU\$ 4.3 billion
TC Tracy	2	1974	AU\$ 4.1 billion
Newcastle earthquake	3	1989	AU\$ 3.2 billion
Queensland floods	5	2011	AU\$ 2.5 billion
Ash Wednesday fires	7	1983	AU\$ 1.8 billion
Victoria fires		2009	AU\$ 1.3 billion
Canberra fires		2003	AU\$ 660 million
Hobart fires		1967	AU\$ 610 million

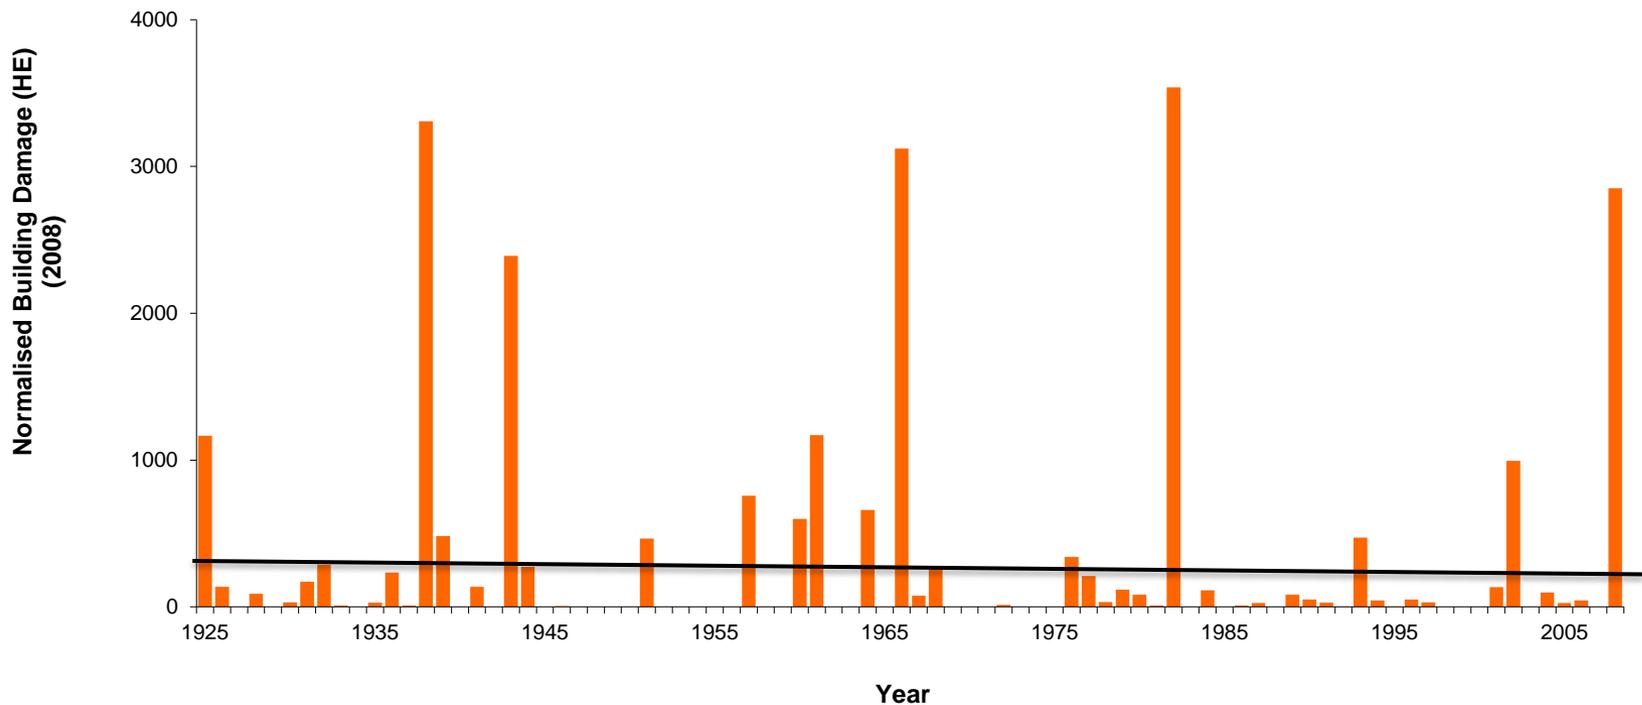

Normalised insured losses as if all events were to impact upon 2011 societal and demographic conditions .  
ICA list since 1967 only. (Source: ICA/Risk Frontiers)

# Normalised building damage due to bushfire, 1925-2009

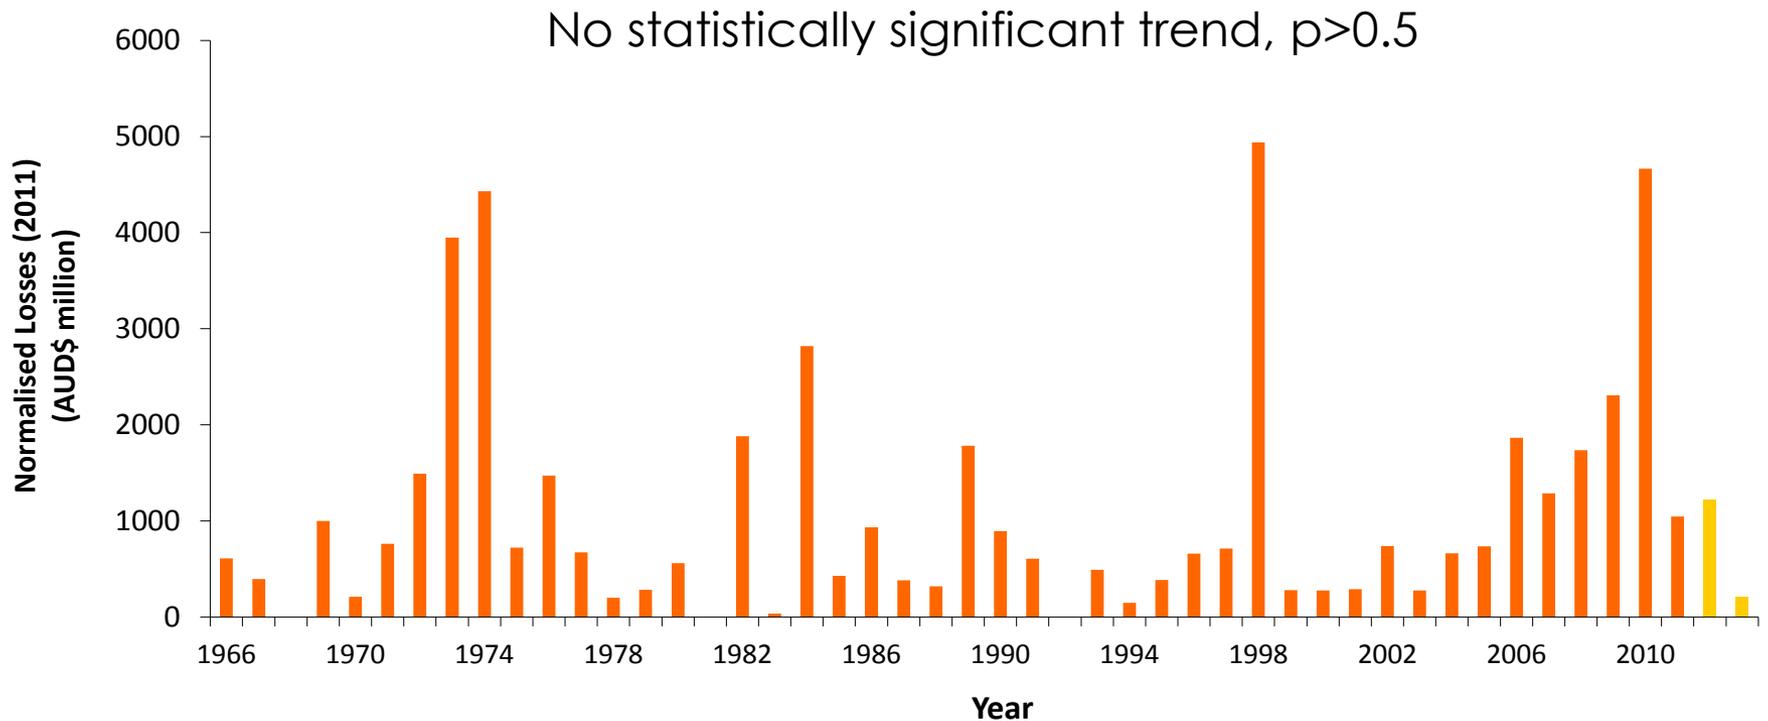

# Normalised building damage due to bushfire, 1925-2009

- No statistically significant trend ( $p > 0.5$ )
- Normalised building losses *decreasing* by 0.672 per year

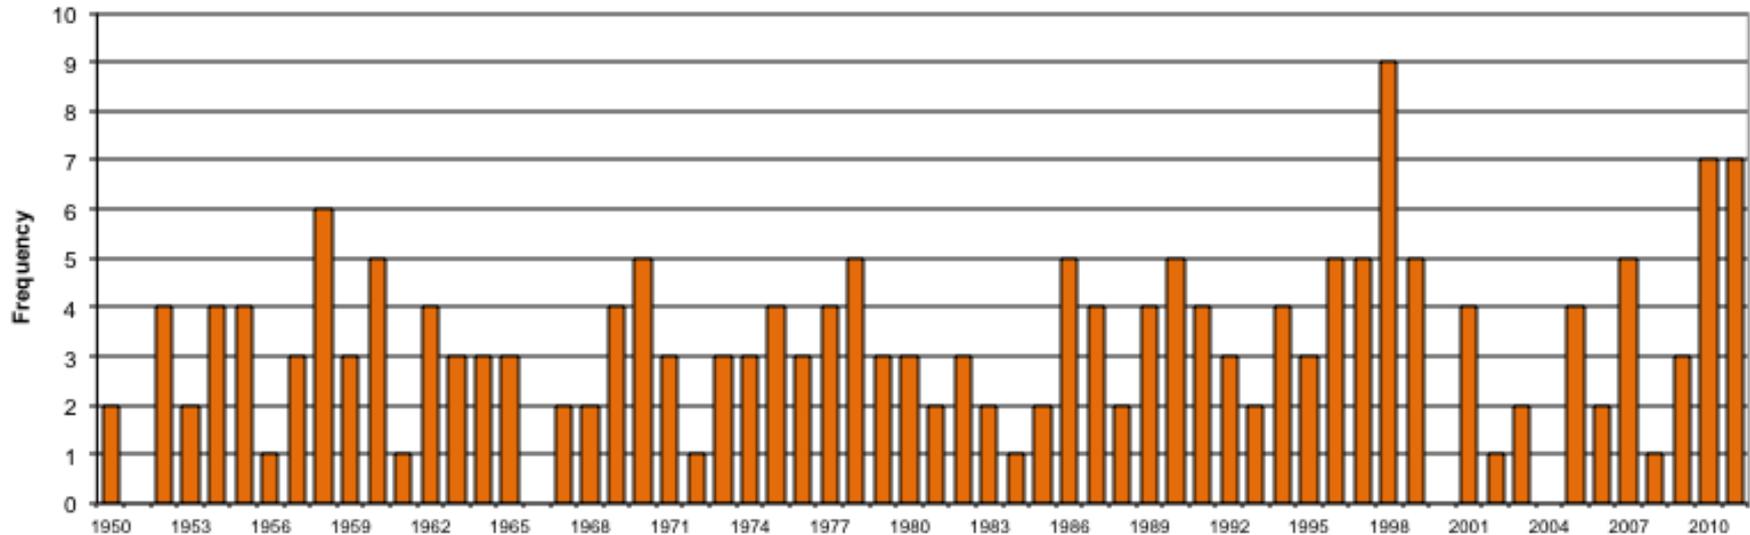

# Normalised Australian weather-related natural disaster losses

(Crompton et al. 2010)

# Australian bushfire frequency

Frequency of events with normalised HE>50, by year

- Normalised losses  $> 50$  HE, i.e. fairly large fires only
- Slope is *not* statistically significant

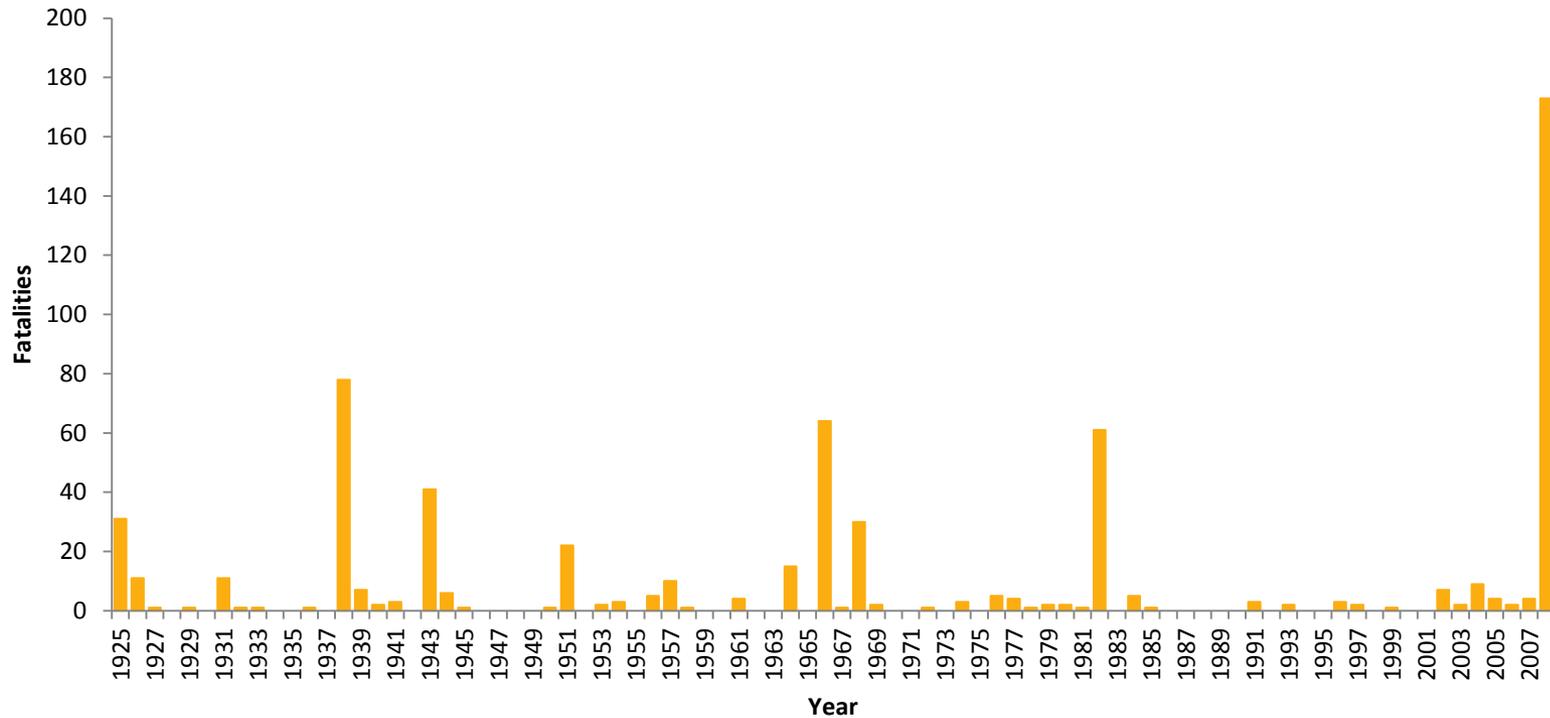

# Natural hazard fatalities

Natural hazard	Deaths 1900–2011	% total natural hazard deaths 1900–2011
Extreme heat	4,555	55.2
Flood	1,221	14.8
Tropical cyclone	1,285	15.6
Bush/grassfire	866	10.5
Lightning	85	1
Landslide	88	1.1
Wind storm	68	0.8
Tornado	42	0.5
Hail storm	16	0.2
Earthquake	16	0.2
Rain storm	14	0.2

(Coates et al. 2014)

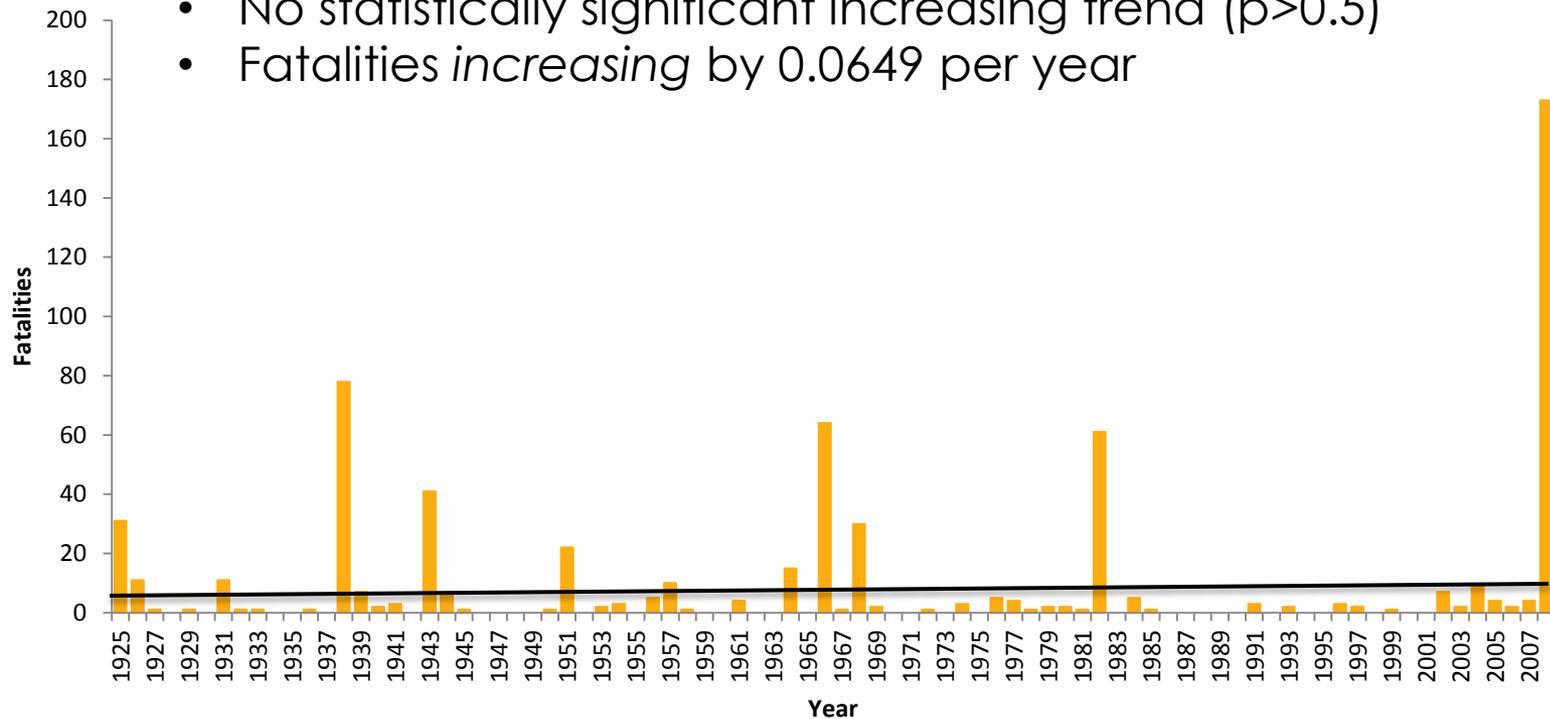

# Bushfire fatalities, 1925-2009

- Bushfires with fatalities occur consistently across time

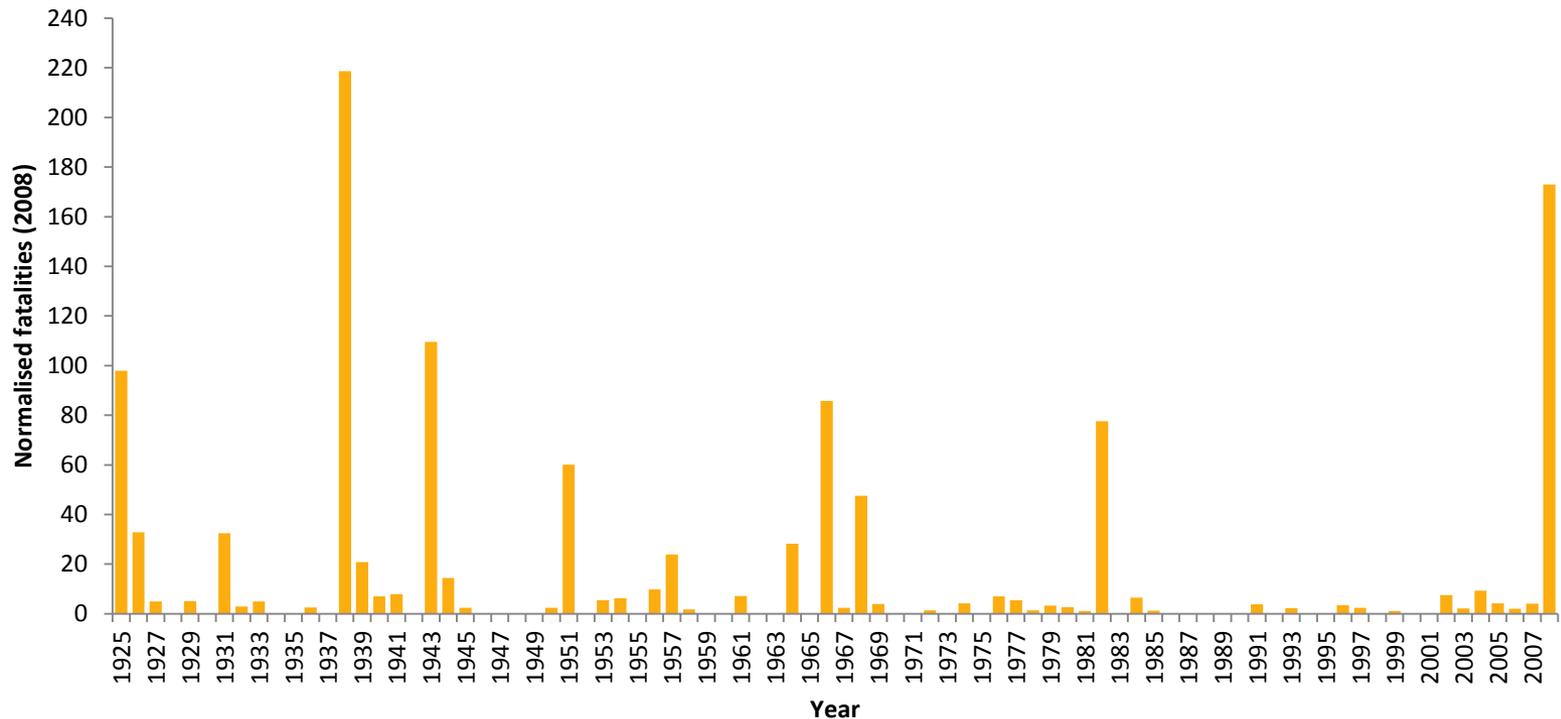

# Bushfire fatalities, 1925-2009

- Bushfires with fatalities occur consistently across time
- No statistically significant increasing trend ( $p > 0.5$ )
- Fatalities *increasing* by 0.0649 per year

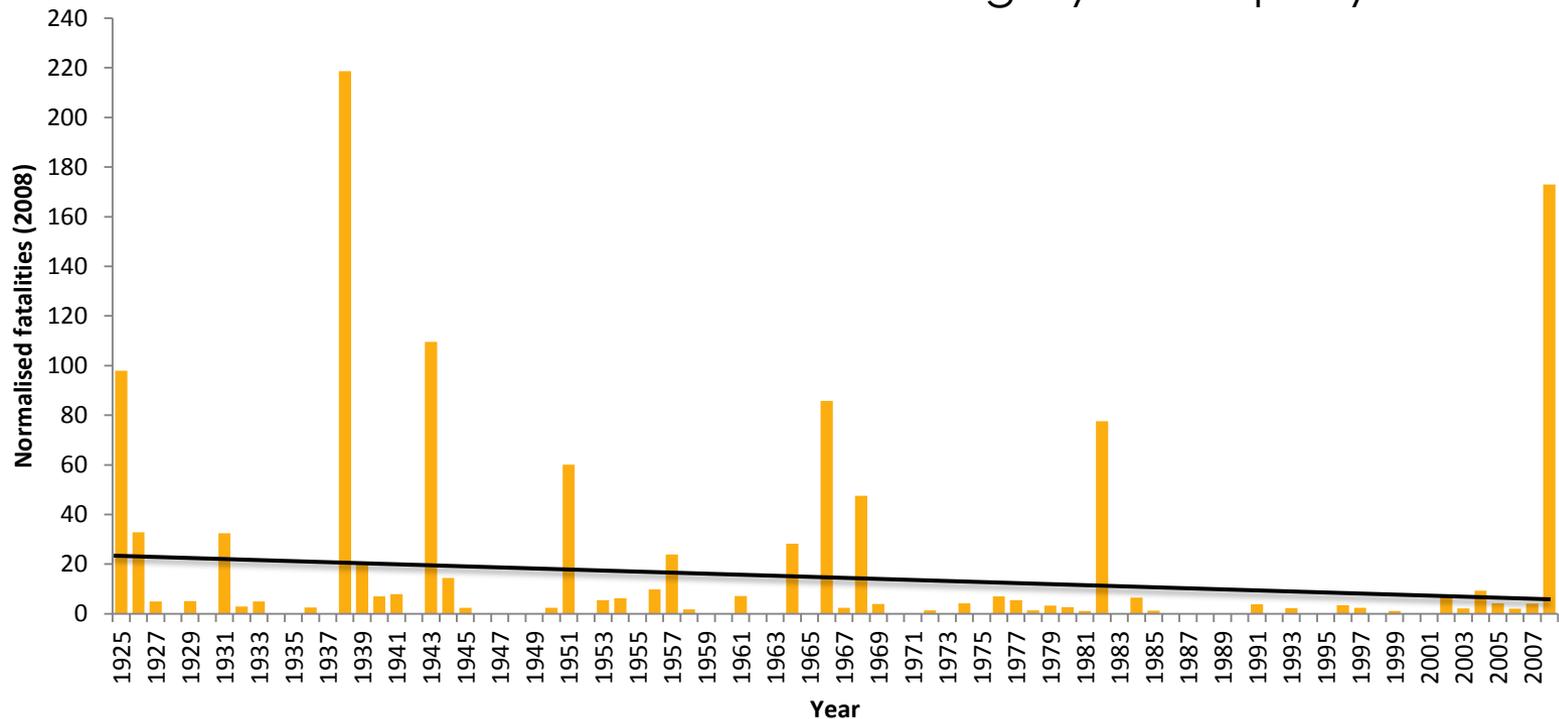

# Bushfire fatalities, 1925-2009, normalised by population

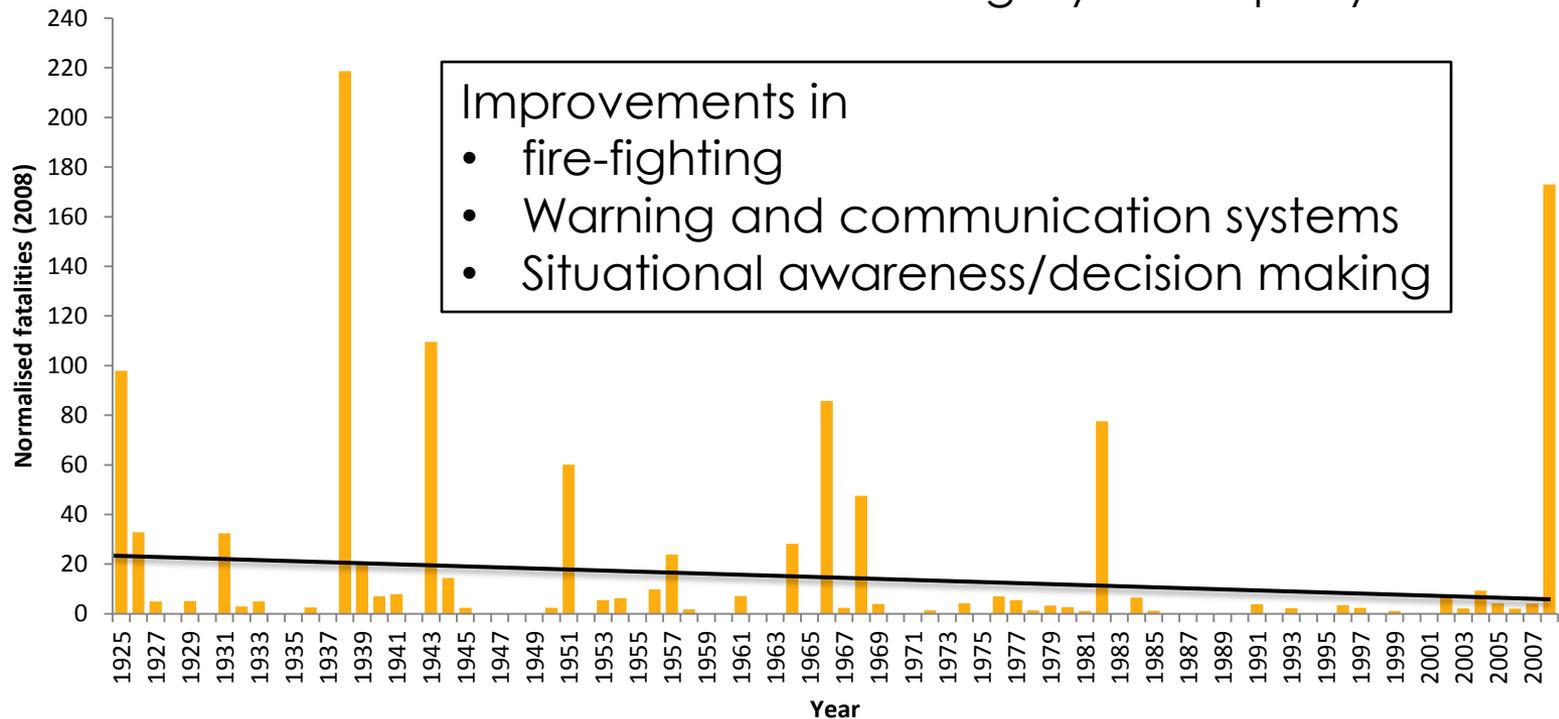

# Bushfire fatalities, 1925-2009, normalised by population

- No statistically significant ( $p > 0.2$ )
- Normalised fatalities *decreasing* by 0.1761 per year

# Bushfire fatalities, 1925-2009, normalised by population

- No statistically significant ( $p > 0.2$ )
- Normalised fatalities *decreasing* by 0.1761 per year

**HAZARDS**CRC

# MODELLING BUSHFIRES AND THEIR CONSEQUENCES

**Felipe Dimer de Oliveira, John McAneney**

Risk Frontiers, Macquarie University, NSW

# MAIN POINTS

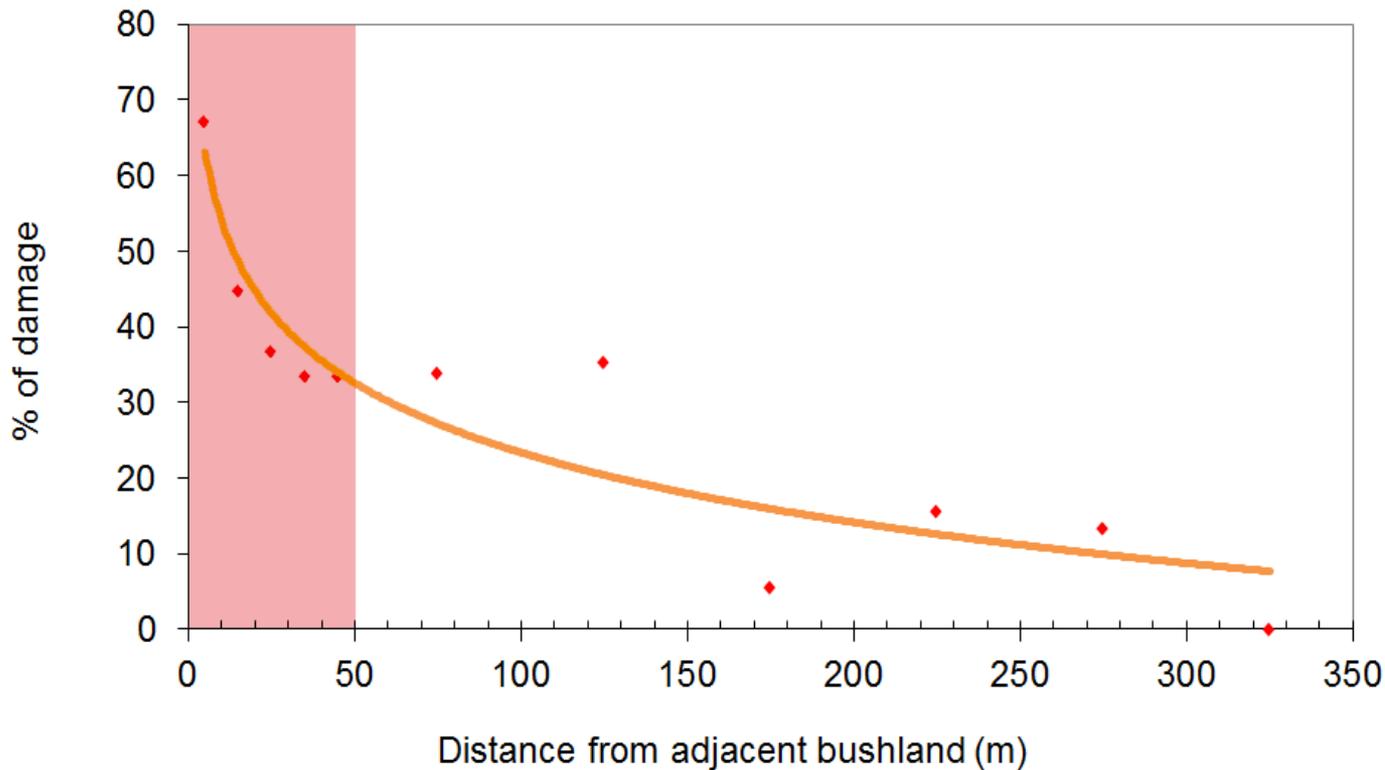

- 1) Importance of distance to bushland as indicator of risk
- 2) Random nature of fires – variability of outcomes?
- 3) Is there a patterns in property damage?
- 4) What can be realistically done for large fires?

# Springwood, Blue Mountains: Oct 2013

# BUILDING VULNERABILITY

Closer to bushland have to contend with radiant and convective heating and direct flames, in addition to increasing ember loading.

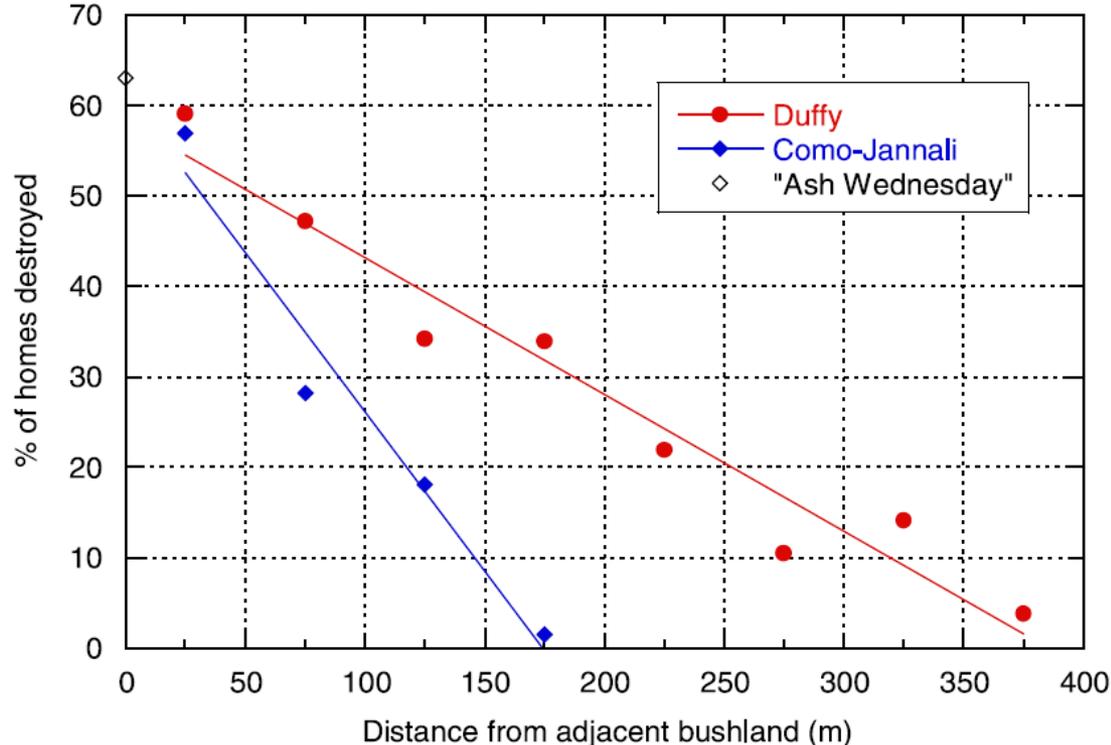

Function of % of houses destroyed with distance to the bush

(Source: Risk Frontiers research)

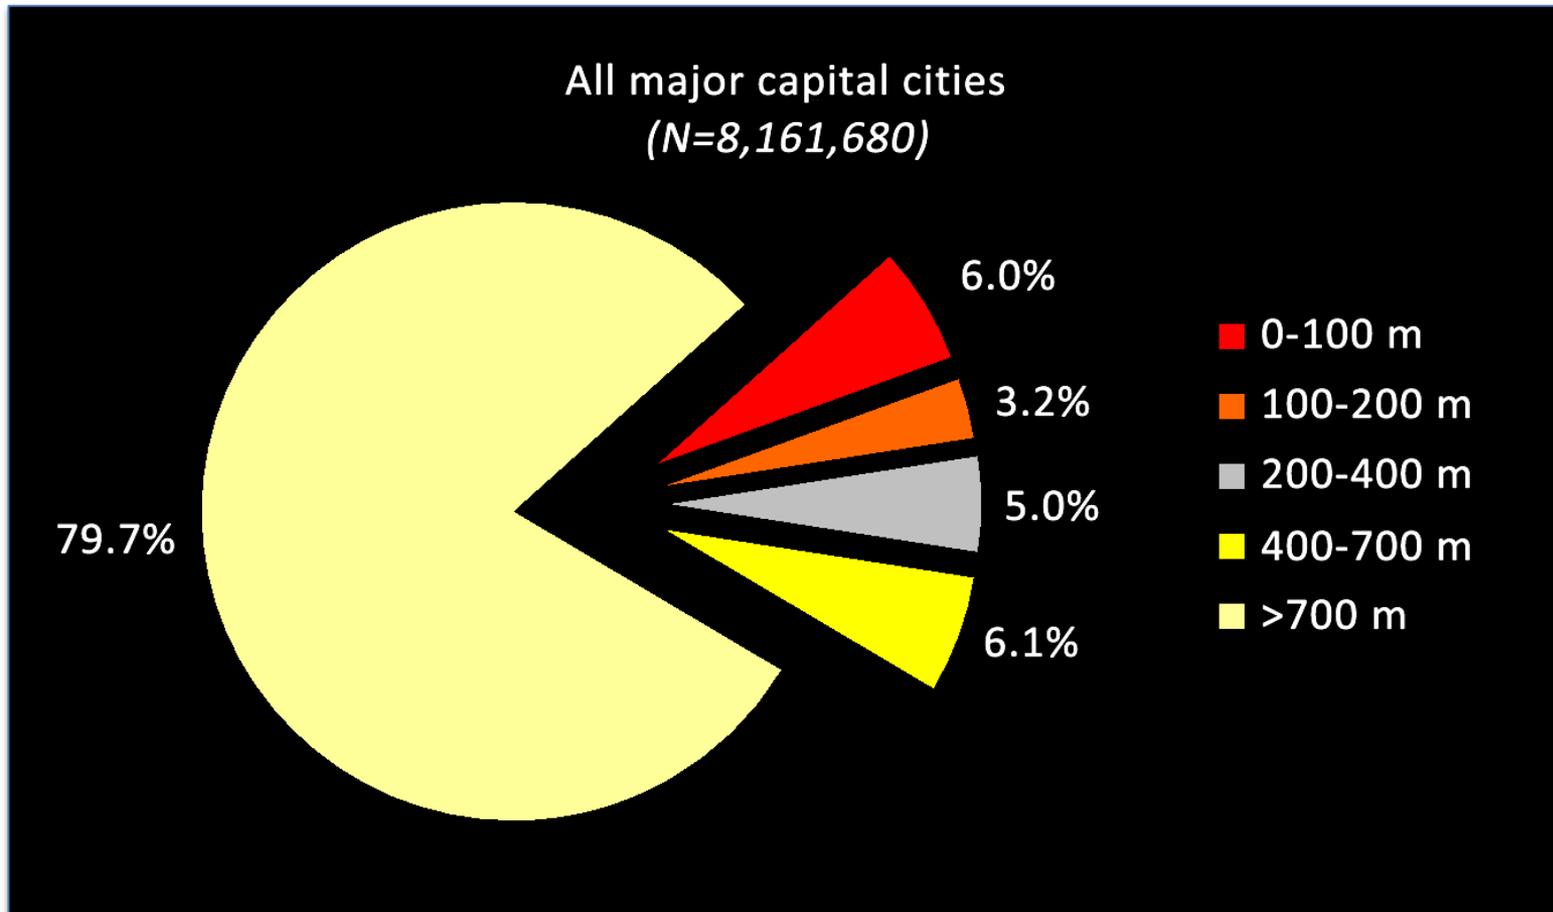

# BUILDING VULNERABILITY

Research shows that beyond 50 m of bushland building vulnerability to ember attack is well modelled as a simple linear function

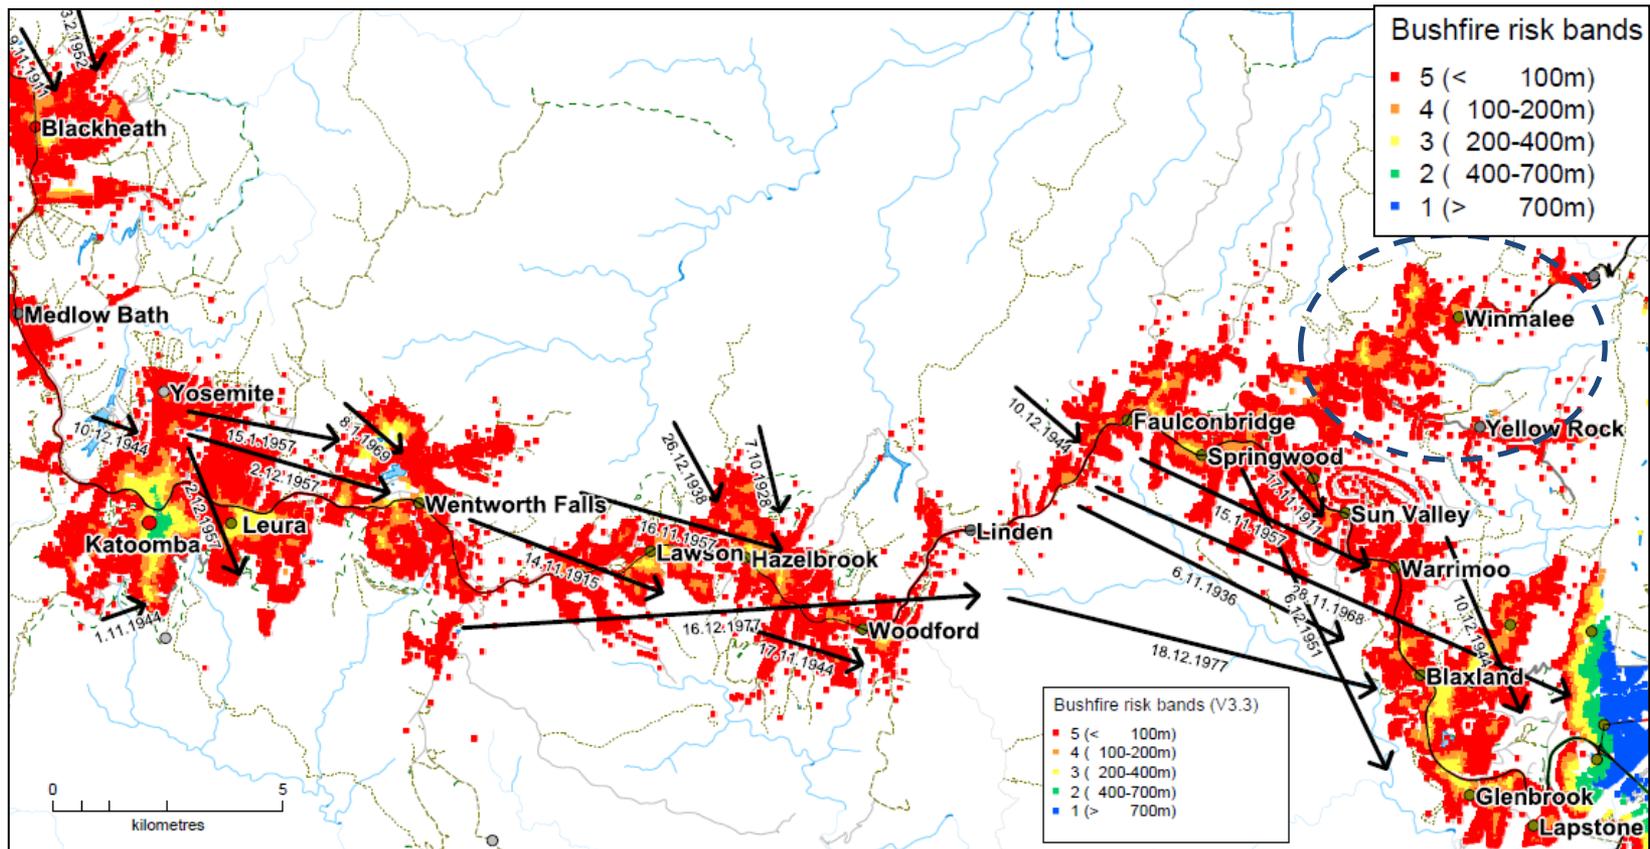

## Bushfire prone properties – about 500,000 in the first 100 m from fire-prone bushland

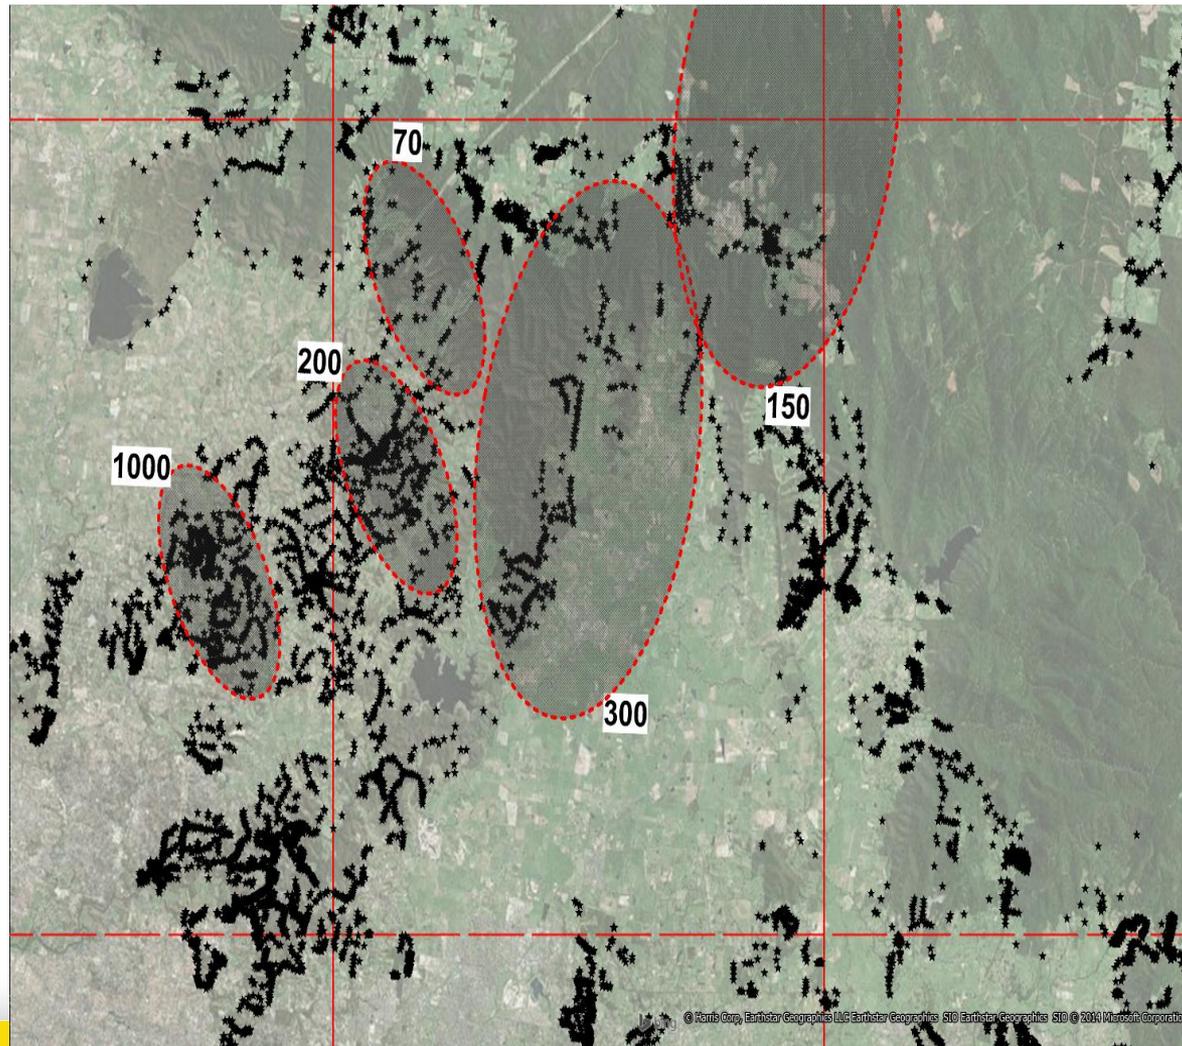

# HISTORICAL BLUE MOUNTAINS' BUSHFIRES

Historical fire trajectories (1911 – 1977) overlain on current exposure

# BUSHFIRE FOOTPRINTS

Number of  
addresses less  
than 100m of  
the bush

# VULNERABILITY VS. BUILDING TYPE

Tasmania Jan 2013

17/10/2013 Blue Mountains

Empirical evidence from other historical major fires:

- 1967 Hobart fires
- 1983 Ash Wednesday fires in SA/VIC
- 1994 Como-Jannali fires in Sydney
- 2003 Canberra fires
- 2009 Black Saturday fires

# BINARY DAMAGE RATIOS

Jan 2013 Tasmania fires

# QUESTIONS?

- 1) What can be done against large fires?
- 2) Should volunteer firefighters be risking their lives to save homes of people who chose to live close to fire-prone bush?
- 3) Should we get serious about land-use planning and in particular distance of homes to bushland?
- 4) Should we focus more on risk communication? – accepting that it's difficult and no one does it well
