# TOWARD MORE EFFECTIVE WARNINGS

Warning #1:

“Severe thunderstorms are expected today with wind gusts exceeding 100 kph.”

*Hazard only*

Warning #2:

“Severe thunderstorms with gusts over 100 kph will result in damage to trees and power lines.”

*Hazard and  
vulnerability*

Warning #3:

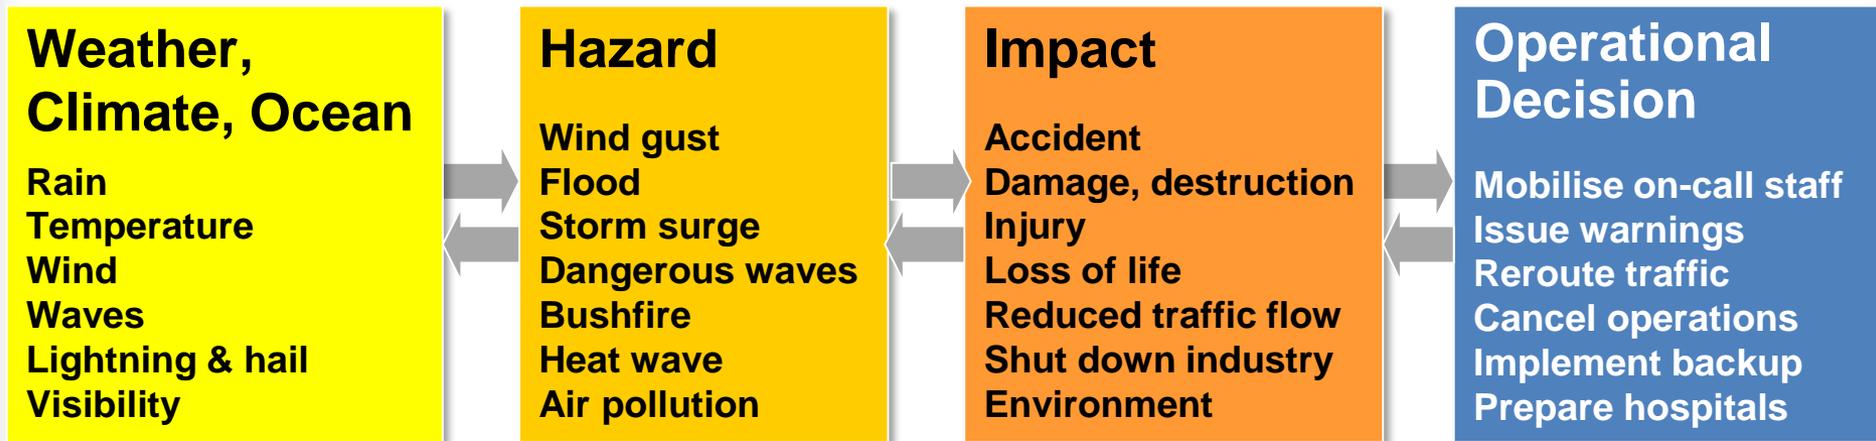

“Extensive traffic delays in Lidcombe may occur due to the risk of large trees downing power lines and blocking roads as a result of severe thunderstorms.”

*Hazard,  
vulnerability,  
and exposure*

Adapted from WMO, 2015

# FROM PREDICTING WEATHER TO PREDICTING IMPACTS

- Coupling weather information to hazard and impact models
  - Bushfire, flood, inundation, air pollution, etc.
  - Structural damage, economic loss, public health, etc.

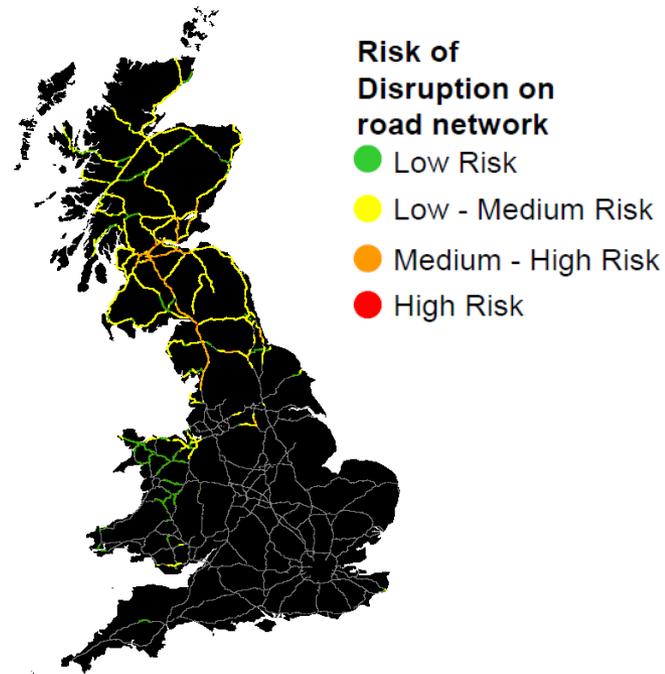

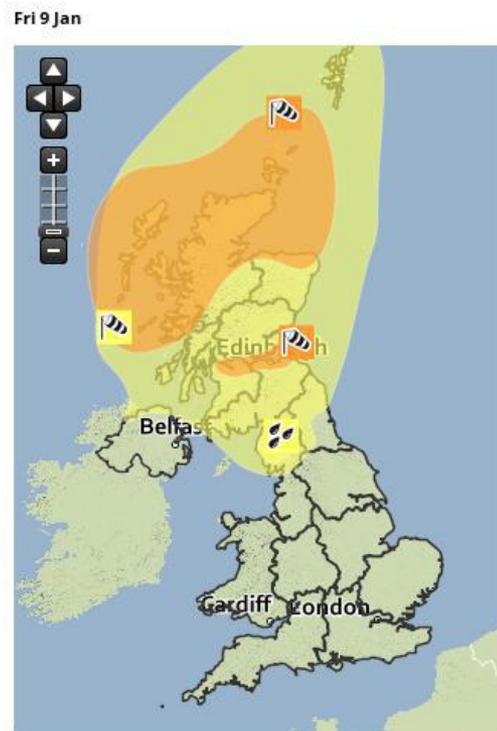

# UK EXAMPLE: VEHICLE OVERTURNING MODEL

Hazard: High winds

Vulnerability: Tall vehicles susceptible to blowing over

Exposure: Location and time (e.g. peak hour)

Credit: Becky Hemingway, Met Office

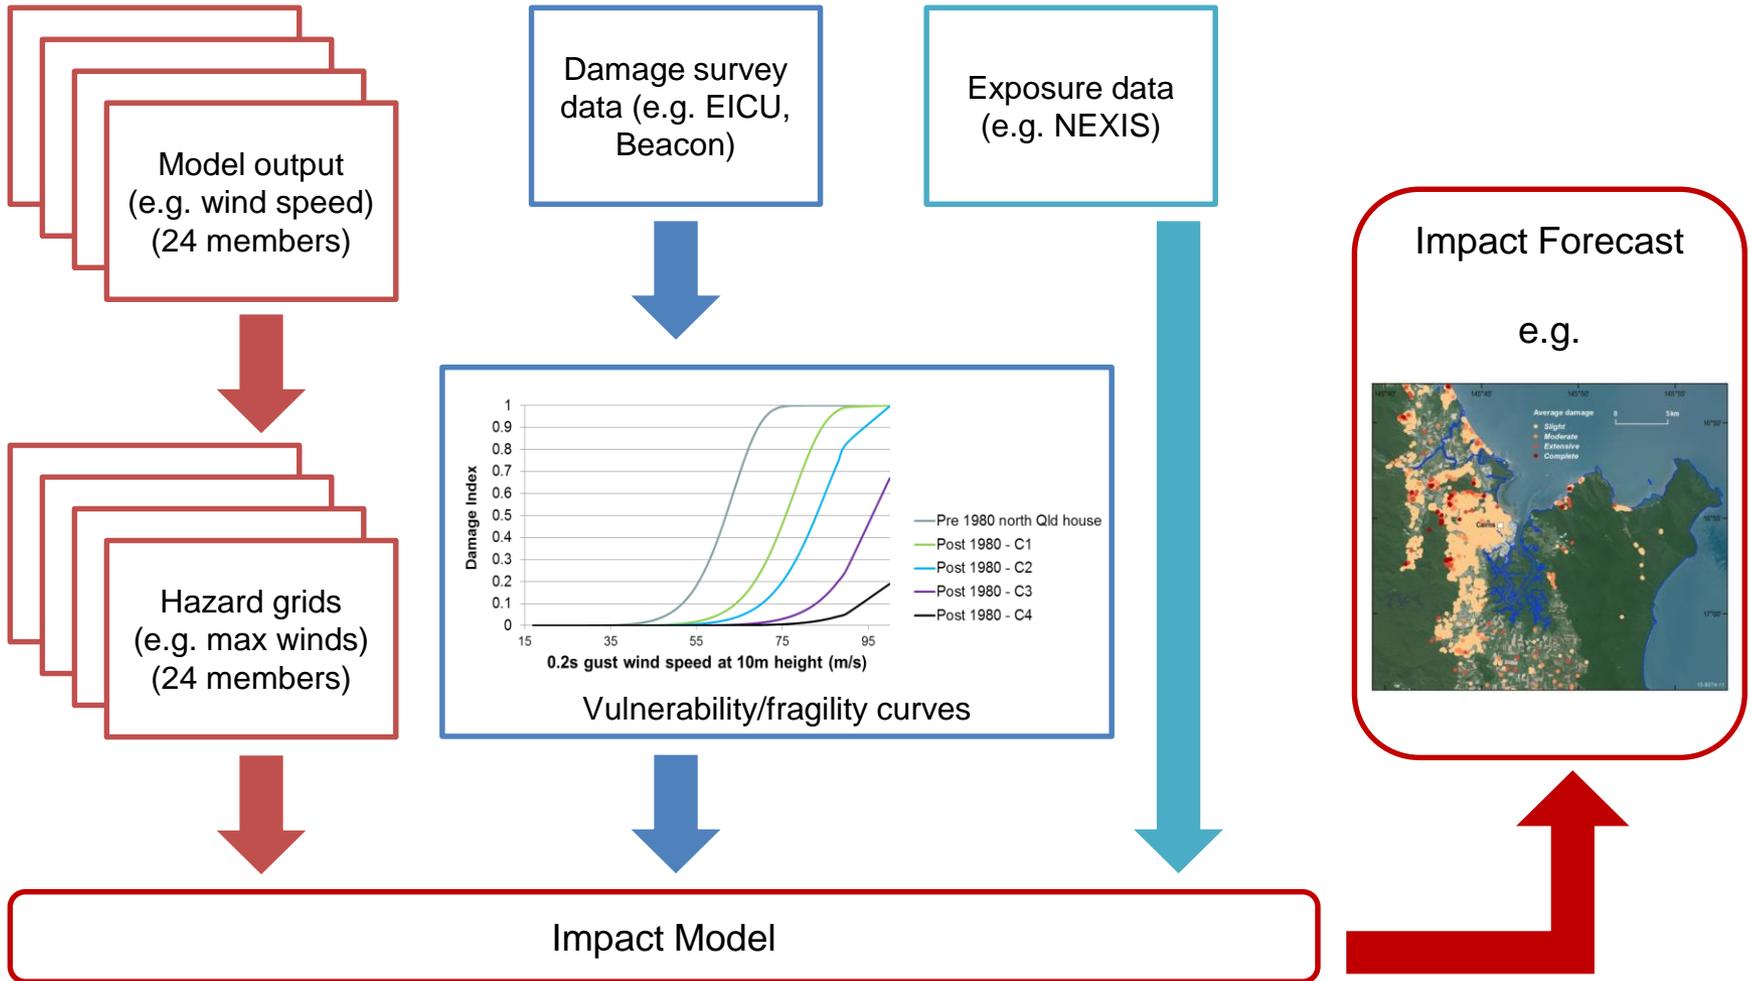

# A PILOT CAPABILITY

How can we make useful estimations of community impacts of extreme wind & rain?

Can enhanced forecasts improve timely mitigating actions for our stakeholders?

# DATA & METHODS

# WIND/RAIN DATA → HAZARD

## ACCESS output

Hydro-meteorological variables:

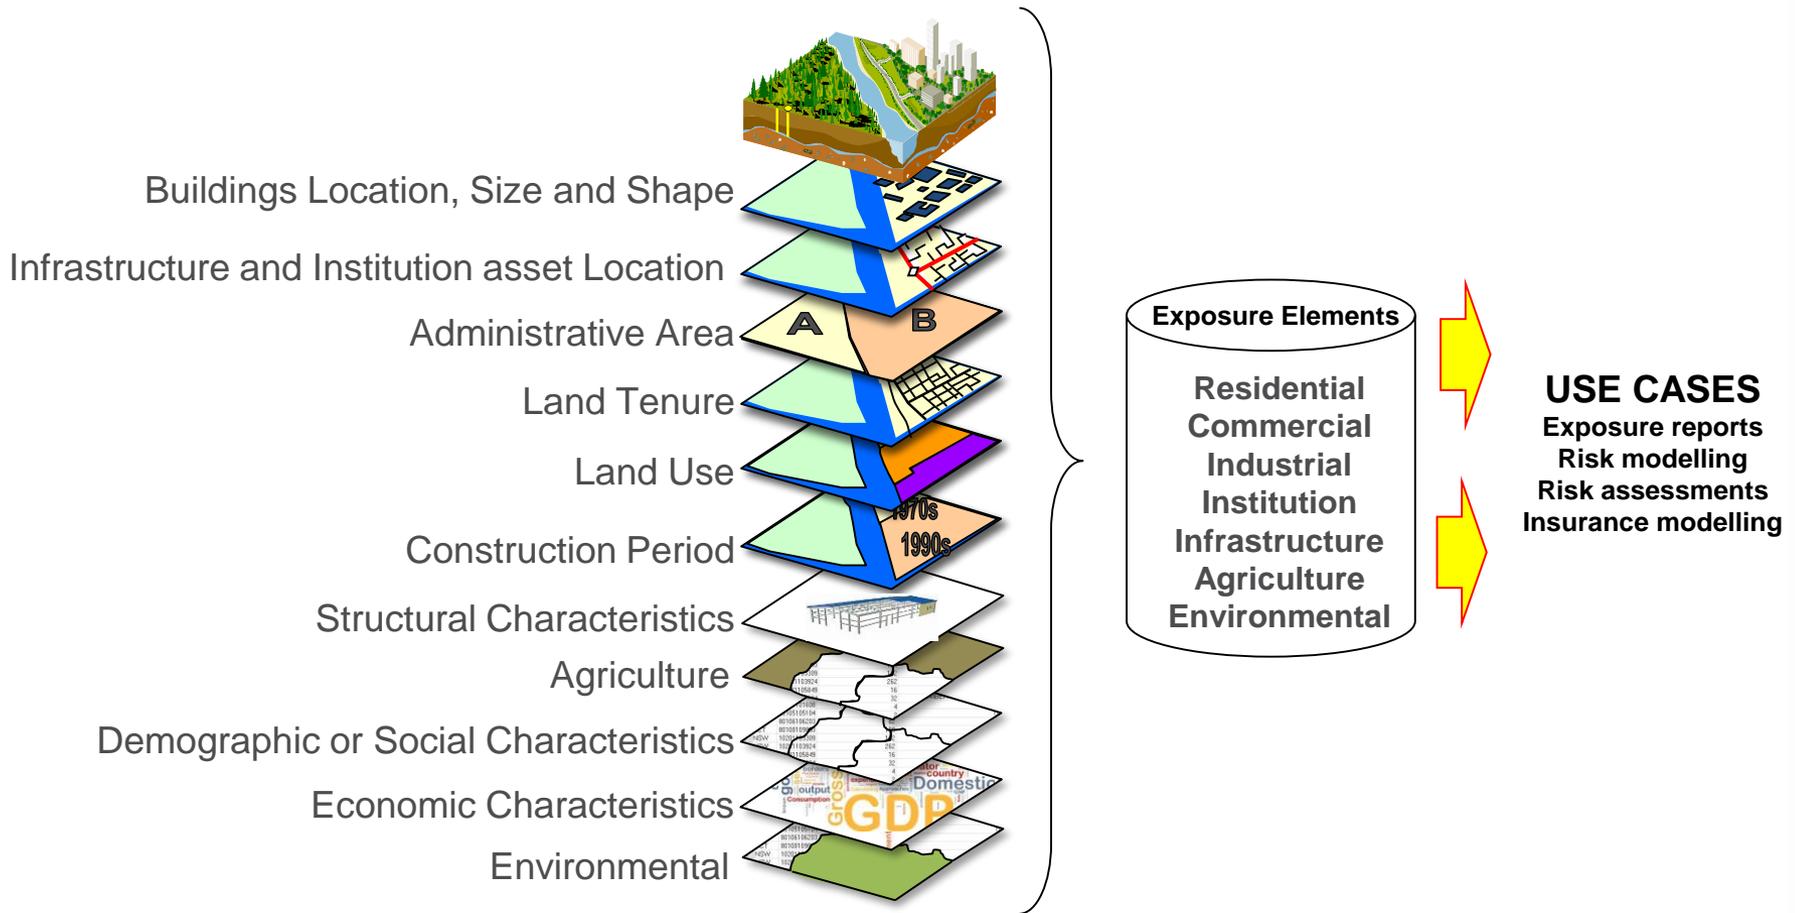

- Wind speed/direction
- Instantaneous rate of precipitation
- Accumulated precipitation

## Gridded hazards

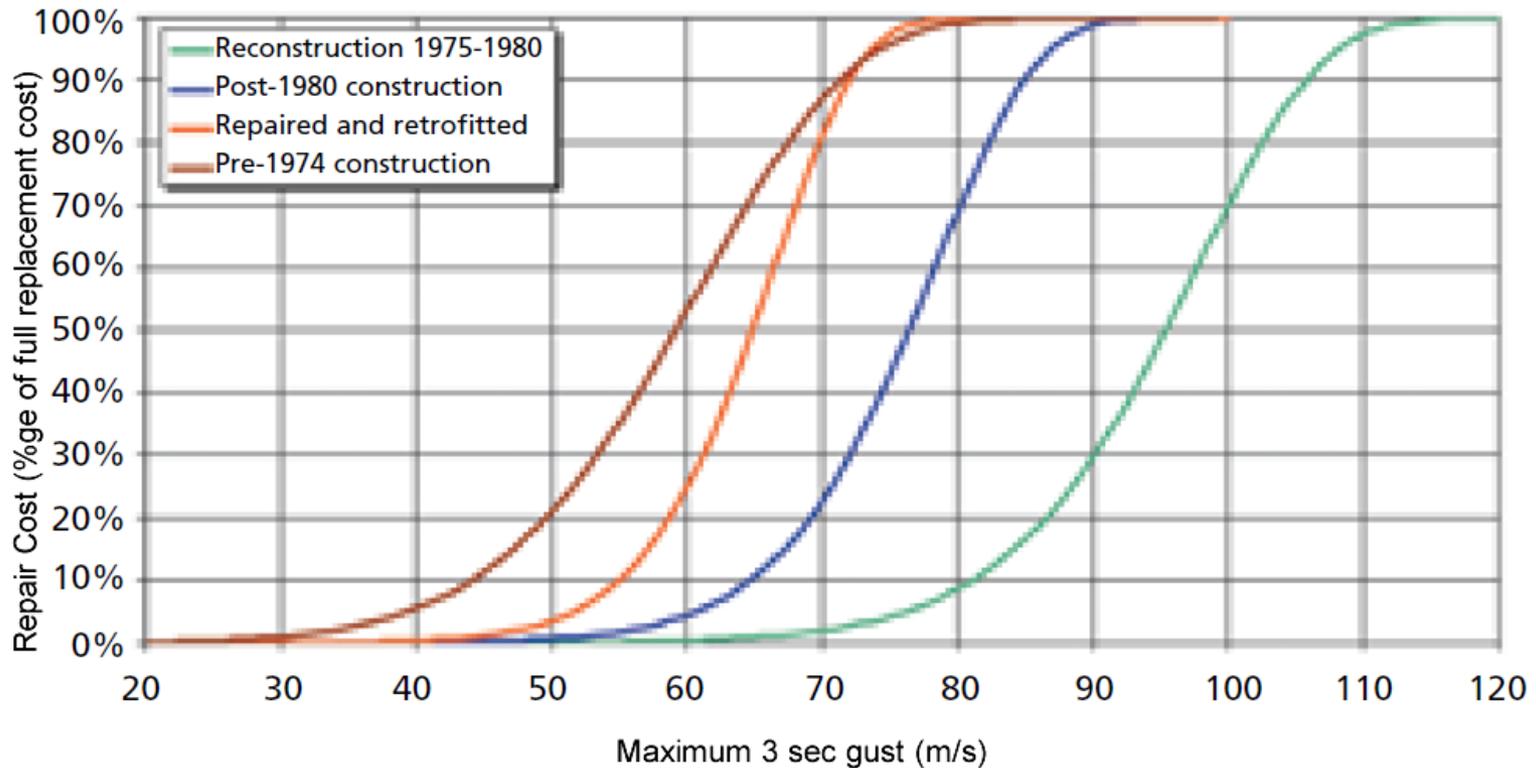

Variables that pose a level of threat to built environment:

- Maximum wind speed (and associated direction)
- Maximum rate of precipitation
- Maximum accumulation of precipitation within timespan (e.g. 1 hour/day)

# National Exposure Information System (NEXIS)

# VULNERABILITY ASSESSMENT LINKS LOCAL WIND GUSTS TO DAMAGE

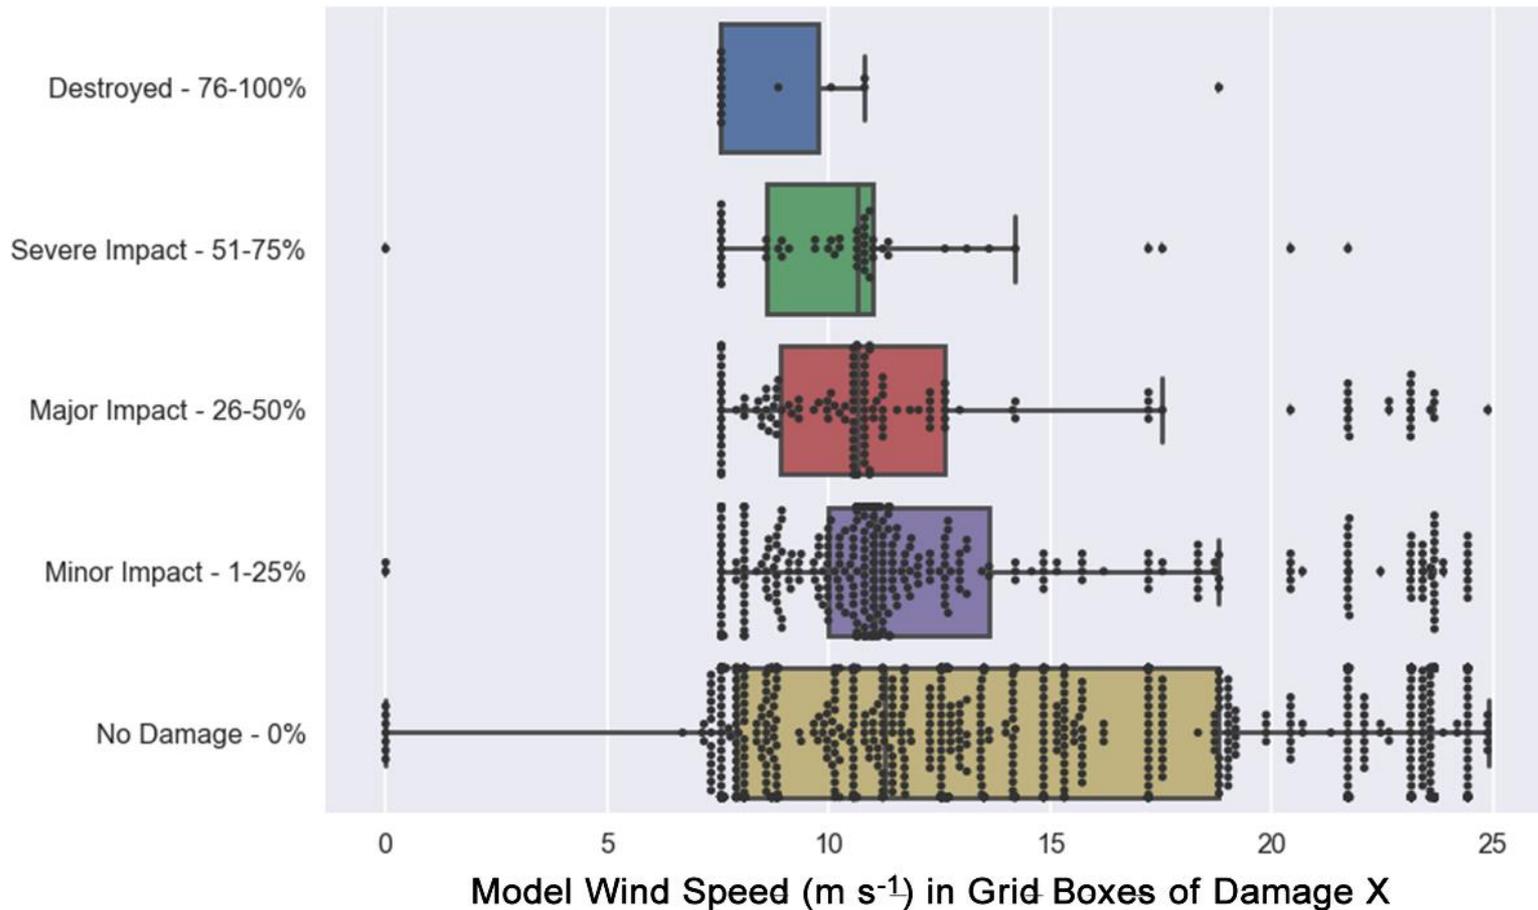

Vulnerability of houses varies with age (on average)

- A TC Tracy peak gust of  $\sim 70 \text{ m s}^{-1}$  ( $250 \text{ km hr}^{-1}$ ) almost destroys a pre-1974 house
- A post-1980 house would only suffer  $\sim 25\%$  damage

# VULNERABILITY ASSESSMENT

## THE UGLY TRUTH THUS FAR

Damage Rating X Based on EICU Data for  
20-22 April 2015

# VULNERABILITY ASSESSMENT

## THE UGLY TRUTH THUS FAR (Part II)

**What derails a nice clean wind / house damage relationship?**

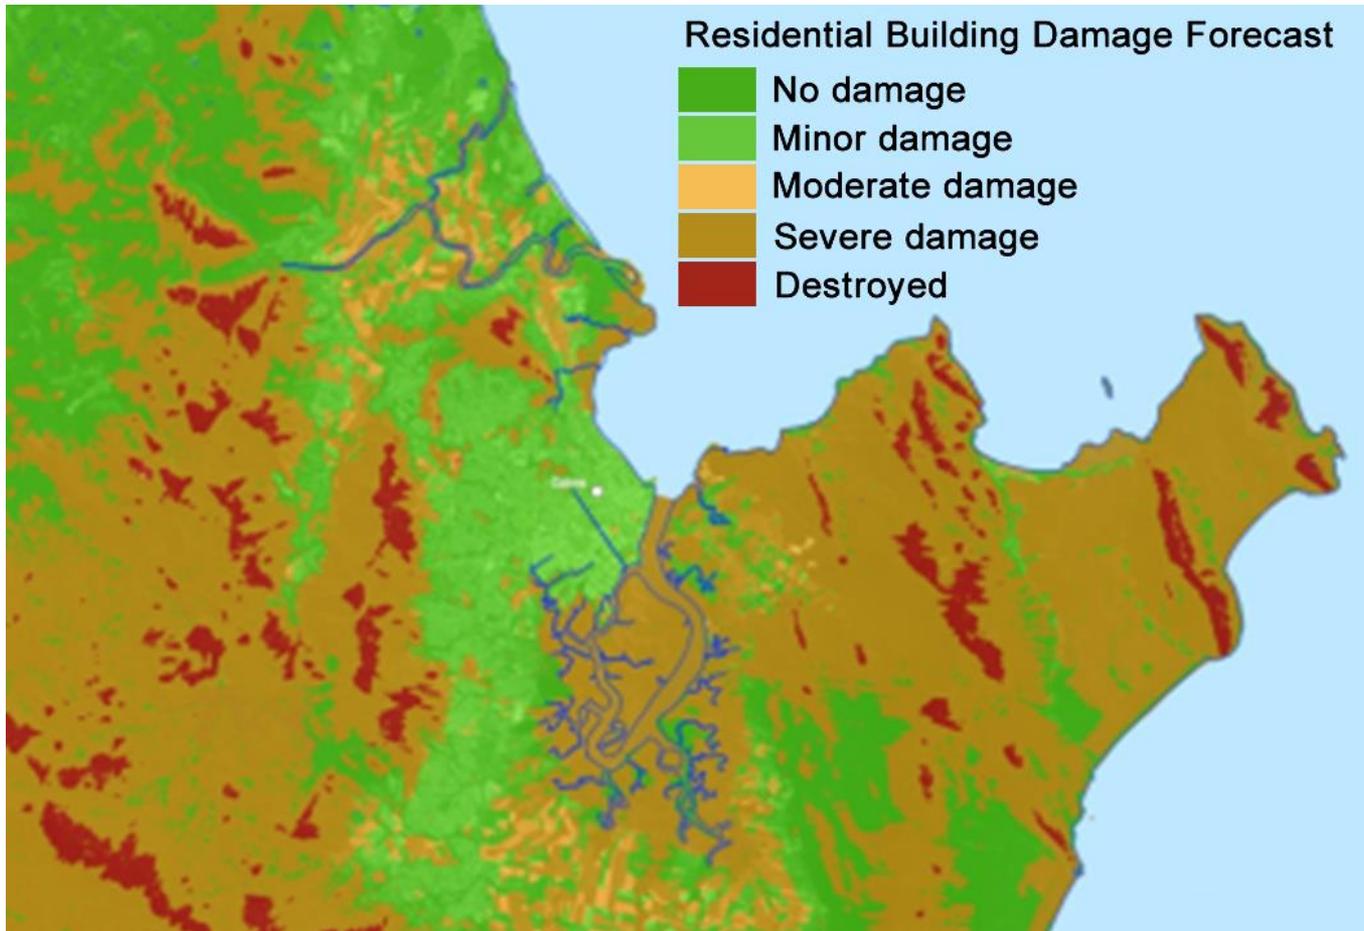

[1] Building design wind speeds in the area mostly exceed  $30 \text{ m s}^{-1}$  → need an event with stronger winds

[2] "Building damage" seems to have been inflicted mostly in an indirect manner

[3] Summative damage reporting inside the damage assessment reports does not permit establishment of clear links to individual hazards

# SPATIAL IMPACT / DAMAGE ESTIMATE

# STEPS FORWARD

1) Consider including additional case studies with stronger winds or cleaner damage report data

- Can we use a measure from multiple damage datasets merged into one vulnerability relationship to express the damage state?

2) Test a range of wind / rain hazard parameters

- (e.g. maximum wind gust)

3) Can SES callout data be augmented to provide additional information?

- (damage magnitude, relation to underlying hazard)

## END-USER ENGAGEMENT OPPORTUNITY

Meet in the SNOWGUM room for breakout session at 2:05pm tomorrow
